come distinct when about 4,000 times the minimum antirachitic dose is administered over an extended period. With 40,000 times the overdosage decidedly toxic effects were produced. After about 2 months the animals began to die, and none of them survived longer than 6 months.

Addition of 3 per cent of calcium carbonate in conjunction with 40,000 times overdosage of activated ergosterol greatly increased the toxic effect of the activated product. On the other hand, a similar addition of disodium phosphate was found to result in no potentiation and may possibly lessen the effect of the drug.

Experiments were further made to study the influence of activated ergosterol in the mother's diet on resistance to rickets in the young. The results showed that no large amount of activated ergosterol is transmitted through the milk, although nursing rats did obtain sufficient ergosterol for partial protection when the mothers were given great overdoses.—Charles E. Bills and Alice M. Wirick, *J. Biol. Chem.*, 86: 117, 1930.

Feeding of Salmonella Enteritidis to Rats on Diets Varying in Vitamin A Content—Indications that the variation in the content of vitamin A in the diet of the albino rat may alter the permeability of the intestinal wall allowing passage of bacteria to other organs of the body led to experiments to ascertain whether symptoms of "food poisoning" might follow the feeding of suspensions of living *Salmonella enteritidis* to rats on diets containing only small amounts of vitamin A.

Nineteen rats, 10 of which had been on a diet deficient in vitamin A, and 9 of which had received a diet with adequate amounts of vitamin A, were fed living cultures of *S. enteritidis*. "Food poisoning" symptoms did not follow the swallowing of *S. enteritidis* by the rats on the vitamin-A-deficient diet but with 2 rats on diets containing adequate amounts of vitamin A the swallowing of *S. enteritidis* was followed by violent diarrhea—apparently a localized reaction. Two rats on the vitamin-A-deficient diet died 6 and 20 days respectively after swallowing the cultures of *S. enteritidis*.

All other rats in the experiment were killed and all animals were autopsied. Of the rats on the deficient diet *S. enteritidis* was isolated from the spleen of 8 of the 10 that had been fed a suspension of this organism. It was isolated from the liver of 2 of these rats, from the lungs of 2, from the kidneys of 1, and the heart blood of 1. *S. enteritidis* was also isolated from the duodenum of 5 of the rats, the ileum of 3, the cecum of 1, and the large intestine of 2.

Many of the cultures from various organs from which *S. enteritidis* was not isolated were found to contain types of organisms which might have come originally from the intestinal tract: coli-like bacteria, proteus-like organisms, staphylococci and streptococci.

As for the rats on the complete diets 3 spleens from rats that had been fed *S. enteritidis* yielded pure cultures of that organism. *S. enteritidis* was isolated from the ileum and large intestine of one rat on a complete diet fed cultures of the organism and from the cecum of another rat similarly treated. The bodies of the 2 rats which had had profuse diarrhea were totally free from *S. enteritidis* 25 days after they had shown "food poisoning" symptoms. The organs of the rats on a complete diet which were fed *S. enteritidis* contained no bacteria of types other than

S. enteritidis. The bodies of 10 rats, some of which had been fed adequate diet and some deficient diet and none of which had been fed a suspension of *S. enteritidis*, were examined with great care but no organisms of the Salmonella group were isolated.—Elizabeth Verder, *J. Prev. Med.*, 3: 489 (Nov.), 1929.

Botulism Resulting from Consumption of Canned Onions—Two cases of botulism occurring in Chicago in January, 1929, were due to the consumption of canned Italian onions served in sandwiches. One case had a fatal termination.

From the victim in the fatal case spinal fluid was collected one hour before death and blood from the heart and a section of the small intestine were taken at autopsy. These specimens were examined for the presence of the toxin and the spores of *Cl. botulinum*. The blood of the deceased contained toxin of B type *Cl. botulinum* but no toxin was demonstrated in the spinal fluid. A culture of B type *Cl. botulinum* was obtained from the section of small intestine.

Two cans of the same brand of this product were obtained from the store where the incriminated can was purchased. One can was a "slight swell" and the other was normal. Toxin and cultures of B type *Cl. botulinum* were obtained from the abnormal can. As small an amount as 0.01 c.c. of the liquor from the "swelled" can was sufficient to cause the death of 300 gm. guinea pigs.

From the opened can which had contained the onions originally responsible for the two cases of botulism a toxic B type culture of *Cl. botulinum* was obtained. An inspection of 400 cans of the same product presumably from the same shipment showed the presence of 5 "swells." These abnormal cans were not sterile, containing anaerobic spore-forming bacteria, none of which, how-

ever, was toxic. Normal cans from the shipment were found to be sterile and non-toxic. The onions in the "swelled" can which were toxic, while differing somewhat in odor and appearance from the normal product, were not sufficiently abnormal to attract attention unless particular care was taken to scrutinize the product closely. The original contamination of the product presumably came from Italian soil where the onions were grown and the processing was not sufficient to kill the spores. The outbreak is unusual in regard to the source of contamination of the food product and it is the first instance in which *Cl. botulinum* has been recorded as growing and forming toxin in canned onions.—Stewart A. Koser and Dorothy O. Reiter, *J. Prev. Med.*, 3: 499 (Nov.), 1929.

A Study of the Vitamin B Complex of Red Kidney Beans and Polished Rice—The technic developed in Dr. Sherman's laboratory (Sherman, H. C., and Axtmayer, J. H., *J. Biol. Chem.*, 75: 207) for determining whether vitamin B or G is the limiting factor in studies of the vitamin B complex (Sherman, H. C., and Spohn, A. A., *J. Am. Chem. Soc.*, 45: 2719). Polished rice was found to be deficient in both vitamins B and G. Red kidney beans were found to contain both B and G, but proportionately more of the former.—J. H. Axtmayer, *J. Nutrition*, 2: 353, 1930.

Studies on the Destruction of Vitamin C in the Boiling of Milk—This paper presents the results of studies with guinea pigs to determine if boiling

milk in aluminum vessels has any particularly destructive effect on vitamin C. The literature on the vitamin C content of milk as affected by various commercial practices is reviewed.

The commonly used methods of determining vitamin C are critically reviewed and the limitations of the method used by the authors are clearly set forth. The following daily doses of raw milk, milk boiled in an aluminum vessel, and milk boiled in a glass beaker were fed: 20, 25, 32, 40, 50, and 62.5 c.c. The authors conclude:

... Twenty c.c. of raw milk and 25 c.c. of each of the boiled milks are practically on a par and 40 c.c. of the raw milk and 50 c.c. of each of the boiled milks are also about on a par. ... Intermediate groups bring out intermediate effects. These data, therefore, support the conclusion that boiling of milk, as in our experiments, reduced the concentration of the antiscorbutic potency to 80 per cent of its original value, and that there has accordingly been a 20 per cent loss. They also show that there was no detectable difference between boiling in the two types of vessels.

They also interpret their data as showing that

... The quality of the winter milk used and obtained from ensilage-fed cows was better than any heretofore reported upon and almost, if not actually, as potent as the best summer milk obtained from cows on pasturage. This points to a forgotten but possible high potential value of milk as a carrier of vitamin C.

Data are presented to show that

The amount of aluminum contributed to Pittsburgh tap water and fresh milk upon boiling in an aluminum vessel is practically nil, being 0.1 to 0.4 parts per million.—

E. W. Schwartz, F. J. Murphy and R. M. Hann, *J. Nutrition*, 2: 325, 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The First Trained Nurse in America Dies—Linda Richards, 89 years old, "the first trained nurse in America," and a friend of Florence Nightingale, died in Boston, April 16, 1930.

Born in Potsdam, N. Y., July 27, 1841, she spent her girlhood in Vermont. She became the first applicant and first graduate of the first school of nursing in the country, that established by the New England Hospital for Women and Children in September, 1873.

In 1875 she became Superintendent of Nurses in Bellevue Hospital, New York, where she helped to form the training school for nurses and where she remained for 2½ years, leaving there to make a study of European hospitals.

In 1885 she went to Japan where she founded a Mission Training School for Nurses in Kyoto, "then she came home and carried on nursing reformation in hospitals for the insane, going from one to another, and leaving each with an improved nursing system." During her life she directed nursing schools in Philadelphia, Boston, Brooklyn, Kalamazoo, Hartford and Worcester.—*A Short History of Nursing* by Dock and Stewart, Putnam, 1920, pp. 147, 159; *History of Nursing and Sociology*, compiled by a Sister of Charity, Brewer-Colgan Co., 1929, p. 43.

pr.

S. More about Industrial Nursing—addressing the Industrial Nurses' Association of Rhode Island, John F.

Kenny, M.D., Pawtucket, gave some timely advice. He urged carefully kept records, for these can be used for reference in accident claims. The records of medical cases particularly should be guarded carefully. They are the private property of the physician and nurse and not open to any employer or department head to read at will.

He warned the nurses not to occupy a position that should be filled by a physician. A nurse should take great care not to treat a case. Under no circumstances should a nurse dispense drugs except on an order from a physician.—*Timely Suggestions, Industrial Nursing Questions, Pub. Health Nurse, XXII, 222 (Apr.), 1930.*

To those who have observed how glibly some industrial nurses hand out drugs to their patients without a physician's order these suggestions of Dr. Kenny's are indeed timely.

One nurse who did distinguished service overseas told with pride about the number of boils and small abscesses she opened. When asked if this did not meet the disapproval of the physicians in the community she said she was always having trouble with them, but she seemed strongly entrenched, as statistics showed that her services had saved her employers a great deal of money. There will be hardship for ethical nurses when other industrial concerns in that community begin to employ them.

Medical ethics in all phases of public health nursing is more difficult than in any other kind of nursing, and many public health nurses have failed either because the ethics of their work was not made clear in their nursing schools or else their judgments were not firm

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

enough to resist the temptation to give treatment without medical advice or to answer the questions all patients are apt to ask about the physicians and their comparative abilities.

The successful public health nurses have had to learn the lesson or drop out. A great deal of the trouble comes from taking young, inexperienced nurses with no public health training and putting them in responsible industrial positions, then expecting them to have good ethics and mature judgment when they are usually left to their own resources. It would be interesting to know how many industrial nurses have standing orders written by the plant physician so they may know what they may do when he is not at hand. It ought to be second nature for a nurse not to treat a patient or dispense drugs without a physician's order.

Public Health Nurses and Committees—Many public health nurses fail because they do not see the value of a board or a nursing committee or both behind them, or if they do have such a committee, they often do not know what use to make of it or their duties in relation to it. This is the gap which exists sometimes between the nurse's practice work in her public health nursing course and the actual problems she has to face when she gets out by herself to do all the public health nursing work in a community. She does not get the contact with nursing committees that she needs either in the city visiting nurse associations or in the rural teaching centers where there is usually a full-time health department and perhaps no committees to whom she has any direct responsibility.

In checking up on advisory visits to nurses in the field made by the staff of one state department of public health nursing, the greatest number of recommendations given had to do with the organization of committees or volun-

teers, and the use to be made of them. Many nurses who have formerly been employed by visiting nurse associations, tuberculosis associations, or Red Cross chapters are at a loss when they find themselves employed by an official agency, with no one to whom they are responsible or who will assist them but the health official or superintendent of schools. If they are wise they prevail upon the health commissioner or the superintendent to let them appear regularly before the county commissioners, the members of the city board of health, the school board, or the parent teacher associations, to present their work and ask for suggestions. There are ways to get and use committees even in official positions if the nurse knows what she wants and needs.

There will be an interesting Round Table discussion at the Biennial Nurses' Convention at Milwaukee in June on advisory committees for official health agencies which will deal with this very subject.

In the meantime, every public health nurse will get many of her ideas on the use to be made of committees crystallized by reading what the April 1 number of the *Red Cross Courier* says about them. The idea and much of the text was copied from the Division of Child Hygiene of the Minnesota Department of Health.

The "*Why of Committee Meetings?*" is given as follows:

1. To transact the business necessary to effective control and development of the Nursing Service
2. To shape the program of work on the basis of current examination of accomplishments and costs in relation to needs
3. To keep in touch with the nurse's activities and any situations affecting the work as they unfold
4. To learn more and more about the work and the health and social needs and resources of the community in order to cope with situations before they become troublesome problems
5. To inspire and be inspired

How often committee meetings should be held depends upon whether there is one nursing activities committee for the whole territory, in which case it should probably meet monthly, or whether there is a county-wide nursing activities committee with sub-committees in different sections of the county. In this case the central committee could meet quarterly if the sub-committees met monthly.

Every nurse would do well to have the following items under "*How Can Committee Meetings Be Made to Amount to Something?*" printed and hung on the wall over her desk:

1. Have a regular date. Begin on time and close on time.
2. Send notices early. Mention in notice any important business that is to come up. Follow up by phone call.
3. Rotate the meetings around different parts of the territory.
4. Have a luncheon meeting occasionally.
5. Have a well prepared plan worked out in advance by the nursing activities committee chairman and the nurse, the chairman assuming responsibility.
6. Give important problems due consideration, if not too urgent, by assigning them to one or more committee members for study and report at the next meeting.
7. Make report of month's work as thought provoking as possible, by use of graphs, spot-maps and pictures; by concentrating on one problem at a time carefully prepared for presentation; by using case stories to make a point, not just to arouse emotion.
8. Include some broad educational topic for discussion when possible, such as the modern practice of immunization, local morbidity and mortality rates as compared with those in like-sized places, local ordinances for protection of milk and water supply, the needs of the pre-school child, and the like. Outside speakers might be invited to lead these discussions.
9. If a study of local needs and resources is being made according to N. H. 273, call for report on one section of the study at each meeting.

10. Have some committee member keep in touch with current literature and present a résumé of particularly pertinent articles.

11. Give some demonstration of nursing technic from time to time, such as bag technic, the inspection of a school child, a prenatal visit, maternity supplies.

An outline of a regular order of business is given which a nurse and committee can easily follow; and if this is carried out with dispatch the meetings will not drag along interminably.

So, too, every committee and nurse could well study and keep a copy near by of "*A Few Ways in Which Committee and Subcommittee Members Can Help between Meetings*":

1. Handle publicity; e.g., prepare newspaper material, give talks, design and make exhibits.
2. Assist with any surveys under way such as of crippled children, the feeble-minded, pellagra cases, midwives, the blind, the tuberculous.
3. Encourage expectant mothers to consult the doctor and nurse regarding care. Inform nurse of all pregnant women and new-born babies.
4. Make and distribute sterile obstetrical packages and loan closet supplies.
5. Organize classes in home hygiene.
6. Help with conferences, weighing days, clinics, health days, immunization and other campaigns and summer round-up work.
7. Provide transportation for patients to clinics, hospitals, or doctors when necessary.
8. Promote hot lunches, assist in securing scales, first-aid kits, and playground equipment for the schools.
9. Arrange for a good health library as a permanent part of the public library or school library in your community.
10. Help with record keeping, preparation of graphs, diagrams and pin maps, office filing and other office work.—

The How and Why of Committee Meetings, Public Health Nursing Service, *Red Cross Courier*, IX, 7: 26, 27 (Apr.), 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

SCHOOLS AND CHILDREN

State-Wide Trends in School Hygiene and Physical Education (as indicated by laws, regulations and courses of study), by J. F. Rogers. Office of Education, Department of the Interior, Washington, D. C. 12 pp. *Free*. Includes health education, etc.

For Better Health Education in Our Schools, by Iago Galdston. Reprint from *Journal of Educational Sociology*. March, 1930. 7 pp. New York Tuberculosis and Health Association, 244 Madison Ave., New York, N. Y. *Free*.

Rest and Sleep, by N. L. Reynolds. National Tuberculosis Association, 370 7th Ave., New York, N. Y. 16 pp. For high school teachers. 5 cents.

The Oregon Tuberculosis Association, Fitzpatrick Block, Portland, Ore., issues a monthly School Health Calendar.

The Philadelphia Health Council and Tuberculosis Committee reports dramatized health talks given in 247 classrooms by Mrs. G. G. Levering, who has appeared as "Martje, Our Health Cousin," or "Sylvia, the Health Gypsy."

Gladys Morse of the Michigan Tuberculosis Association visits the schools garbed in buckskin, and tells children fascinating Indian legends with health "morals." Miss Morse recently became "Kee-she-goo-quā" (Princess of the Sky) through adoption by the Chippewas.

A list of 167 Ohio high schools offering programs of health and physical education worthy of recognition by colleges and universities as one of the 16

units of entrance credit has been issued by Dr. D. Oberteuffer, supervisor of health and physical education, State Department of Education.

A Health Project, by Doris Powell. *Public Health*, Michigan Department of Health. Feb., 1930. After a puppet show by the Michigan Tuberculosis Association the 3d and 4th grades worked out a show of their own.

... a cardboard box for the theatre, a roll of white paper for the screen, and to paste silhouette figures in black on the screen to illustrate our story. Two small poles were inserted, one on each side of the theatre, and upon one the "film" was to be rolled. As the picture progressed the film was to be wound off on to the other pole.

The Story of Frankie Fuss is given, and how the project extended into arithmetic, drawing, language, etc. *Free*.

GIRLS

The cover page has the atmosphere of a department store or specialty shop, this booklet entitled "Better Health for Young Women," issued by the Department of Health, Winston-Salem, N. C. 8 pp. Line cuts. Credit to Syracuse Department of Health for "the cuts and for much of the material." Headings: "The Modern Girl's Health," "New Styles in Health," "Flappers," "It's Smart to Be Healthy," "How to Be Beautiful," "Health for Sale!" A self-scoring chart scores some readable points. With the full credit statement on the back page it might have been better without the Syracuse credit lines under authors' names. *Free*.

What a Whale of a difference a little Health makes in the Everyday Life of

a Girl. Cleveland Health Council, 715 Superior Ave., N.E., Cleveland, O. For 'teen-age girls. 4-page folder. Inside: "Want to Be Popular?" The recipe includes Pep, Poise, Personality. Their ingredients given. *Free*.

DIPHThERIA

New York State chronology for January 17–February 19, 1930: Monthly meeting of State Diphtheria Conference Committee discussed case and death rates of cities already selected for intensive campaigns, showing need for special effort in some communities; State Federation of Women's Clubs and State Congress of Parents and Teachers have asked local groups to help the campaign; State Committee is preparing outlines of local campaigns for large and small places to send in response to inquiries; special window exhibits were prepared; revised and re-ordered its educational materials and adapted some New York City items for use in other cities, making a total of 14 items.

Diphtheria and Its Eradication, by William H. Park. Westchester Tuberculosis and Public Health Association, 8 Church St., White Plains, N. Y. 8 pp. 5 cents. Address to a parent-teacher association.

Copies of practically all of the following items will be supplied upon request:

Radio: Prevent Diphtheria, by New York City Health Department; Diphtheria in the Discard, by Connecticut State Department of Health; Diphtheria Prevention, by Philadelphia Department of Health.

State department bulletins: New Jersey (Mar., 1930)—Who Gets Diphtheria Now-a-Days? with diagrams; North Carolina (Feb., 1930)—Project about Diphtheria at the North Carolina College for Women—includes text of letters written by college students to home-town children—examples of some effective copy to be sent into the home.

City department bulletins: Milwaukee (Feb., 1930)—Diphtheria Caused Twenty-five Deaths in 1929—Why?; Albany described the local campaign; Middletown, N. Y., reports the "first case of diphtheria since August, 1925, in which the infection could not clearly be shown to have been contracted outside the city." Due to impression of family that a several years' old Schick-test was T. A. T.

ART

Child Health Day in Iowa. State Department of Health, Des Moines, Ia. 20 pp. Contains 14 examples of the use of silhouettes. *Free*.

Effective silhouettes illustrate Shopping for the Family Physician. *Hygeia*. Mar., 1930.

Gay line sketches illustrate "How about a Courtesy Campaign?" *Safety Education*, 1 Park Ave., New York, N. Y. Apr., 1930. *Out of print*.

The Infant Welfare Society of Chicago report for 1929 contains a group of 5 photographs, one to a page, and each with a descriptive caption of 4 to 7 lines.

"Improving Picture Production," by W. E. Barr, of the Eastman Kodak Company, in *Editor and Publisher* (Feb. 15, 1930), emphasizes that pictures intended for newspaper reproduction should be clear, sharp and contrasty, and that the print should be made on a "hard" paper.

The *New York Times* manual of Typographical Standards says:

The secret of good newspaper reproduction of illustrations is contrast. Clear, sharp, contrasty photographs will produce good cuts. Flat photographs—prints that have no strong separation of tones—will produce poor cuts.

FILM SLIDES

A new film strip consisting of 18 pictures illustrating hazards in the modern American home and 9 explanatory slides has been completed by the National

Safety Council, 20 N. Wacker Drive, Chicago, Ill. The mimeographed lecture on important phases of home safety will be loaned free and a projector rented for \$1.00 a day. For members.

The tuberculosis motion picture, "Consequences," has been made into a film slide strip by the Spencer Lens Company, Buffalo, N. Y.

MAGAZINE ARTICLES

The Dentifrice Racket, by Catherine Hackett. *New Republic*. Jan. 15, 1930. Good reading.

Eyes Right, by Fassett Edwards. *Colliers*. Mar. 1, 1930. Danger signs; what not to do.

How to Keep Sane by Maintaining the Health of the Emotions, by G. F. Alsop, M.D. *Woman's Journal*. Mar., 1930.

Infantile Paralysis—How Dangerous Is It?, by George Draper. *Harpers*. Feb., 1930.

This Question of Birth Control, by D. D. Bromley. *Harpers*. Dec., 1929.

This Will Be Smallpox Year. *Literary Digest*. Mar. 15, 1930. From *Ohio Health News*.

SAFETY

Home Accidents and Home Economics, by S. J. Williams. *Journal of Home Economics*. Mar., 1930.

"Every 17 minutes another traffic death," is illustrated by the National Safety Council by shading 17 minutes on a clock face.

A page advertisement, paid for by 32 firms, headed "A Message to Parents—The Street is a Poor Playground," was one of a series supported by merchants in coöperation with the Toledo Safety Council.

The News Letter, National Society for the Prevention of Blindness, 370 7th Ave., New York, N. Y. (Feb., 1930. *Free*), states that a 70 per cent cut in eye injuries resulted from the following:

A large blackboard, 4 feet by 8 feet, was placed at each of the three entrances to the factory of the Autocar Company. Twice each week safety messages were inscribed on these boards in three brilliant colors of chalk and in a striking design. Here are three typical messages:

"You don't want to peddle lead pencils on the street.—Goggles Prevent Blindness."

The design used was a large drawing of a pair of goggles. A second message read as follows:

"The most delicate organ in your body. One flying chip may blot out your sight.—Wear Goggles."

A drawing of an eye was used for the design. Another message read as follows:

"Don't try to be your own eye doctor. Dangerous infection is caused by removing particles with a toothpick, finger or handkerchief.—Refer all eye troubles to the nurse, and do it at once."

POSTERS

Two posters to encourage the care of children's teeth have been issued by the Bureau of Dental Health Education, American Dental Association, 58 E. Washington St., Chicago, Ill. *Write for details*.

A new poster by C. Le Roy Baldridge has been issued for nursing services by the National Organization for Public Health Nursing, 370 7th Ave., New York, N. Y.

One copy of a new poster accompanies every issue of *Safety Education*, National Safety Council, Park Ave., New York, N. Y. *Sample free*.

A series of 12 bulletin board posters on automobile safety has been started by Employers Mutual Indemnity Corporation, Wausau, Wis. *Free*.

An original poster for display on bulletin boards in the plants of the Western Electric Company is issued every month by R. T. Barker, director of health and safety, 195 Broadway, New York, N. Y.

NEW NAMES

National Health, 5, Favistock Square, London, W. C. 1, England. Now *Mother and Child*, having become the

official organ of the National Council for Maternity and Child Welfare.

The Poster Magazine is now *Advertising Outdoors*, 165 W. Wacker Drive, Chicago, Ill. *Sample copy upon request.*

PSITTACOSIS

Psittacosis (pronounced sit-ak-o'-sis)—"A disease of parrots communicable to man, marked by high fever and pulmonary disorders."—Middletown, N. Y., Board of Health *Bulletin*.

"One of the greatest dangers of any possible epidemic disease lies in the hysteria that develops in connection therewith. Fear plays its part in increasing morbidity even while the infection is definitely declining."—*American Medicine*, New York, N. Y. Feb., 1930. Another opportunity for careful publicity.

"Poor Psittacosized Polly"—*Literary Digest*, Feb. 8, 1930.

A cartoon, "The Timid Soul," by H. T. Webster. In *New York World* and other dailies. Feb. 3, 1930.

READING LISTS

Bibliography on the Relation of Clothing to Health, by O'Brien, Peter-

son and Worner. Superintendent of Documents, Washington, D. C. 25 cents.

The Parents' Bookshelf. American Library Association, 520 N. Michigan Ave., Chicago, Ill. Health, sex, nerves, etc. 10 cents.

REGRETTABLE—UNNECESSARY

A city department of health issues its monthly bulletin and its annual report on a shiny, white paper not pleasant or easy to read.

Public Education in Mental Hygiene—says *Mental Hygiene Bulletin*:

The widespread development of interest in mental hygiene in recent years has greatly stimulated educational activities in this field, and leaders in psychiatry and mental hygiene concerned with the guidance of these activities on a sound basis have agreed that the time has come for an evaluation of the methods and material employed in this work in various parts of the country.

... Determination of standard lines along which the methods and contents of lay education in mental hygiene should be developed in the future, and the formulation of a plan for recruiting writers and speakers trained in the art of simplifying technical material for the benefit of non-professional groups, are among the results it is hoped will come from the study.

BOOKS AND REPORTS

The Psychology of Learning Applied to Health Education through Biology—By Anita Duncan Laton, Ph.D. New York: Bureau of Publications, Teachers College, Columbia University, 1930. 103 pp. Price, \$1.50.

This is a report on an experiment made in the Lincoln School of Teachers College, Columbia University, to test the validity of certain methods of teaching. The study is described as an attempt to apply the facts and principles established by work in the psychology of learning to the teaching of one unit of subject matter to junior high school biology.

The unit on prevention and control of communicable diseases was chosen for experimentation because its contribution to health education seems obvious and important. The chosen objectives were education for health (useful to the student now and later in life) and satisfaction of commonly accepted standards regarding subject matter for a course in biology. The diseases chosen were those having the greatest value for study by 9th grade pupils in New York City, because of their incidence in this region. Two sections of the 9th grade were chosen for the experiment, one being taught in accordance with the principles of educational psychology, and called the experimental group, and another section called the control group. Elaborate comparisons of ability, interest and achievement were made in order that the conclusions drawn might be well based. The two sections were found sufficiently similar, both in information and interest.

Discussion is said to have been more animated in the experimental class. There were conferences between the teacher and those students who were to give reports to the class, and erroneous statements were corrected before the class. Interestingly, the experimental class laid emphasis in its reports on means of prevention and control of disease, while in the control class there was more emphasis on symptoms and treatment. Since these students are school children, not nursing or medical students, knowledge of prevention seems much the more important. The experimental group chose the diseases most valuable for such studies and showed greater ability to recognize measures for preventing outbreaks of these diseases.

The author is well satisfied with the application of the method. The experiment is well presented and worth reading by teachers of biology, and by others who promote health education and wish to make their presentations of such topics forcible and well retained.

SAMUEL W. HAMILTON

Physiology and Health—By C. E. Turner. Boston: Heath, 1929. 282 pp. Price, \$1.00.

This excellent little book, one of the Malden Health Series, is intended for pupils in the late junior high, or early senior high school.

The arrangement and treatment of the subject matter, though conventional, nevertheless shows an understanding, and appreciation of the mental capacity, and the interests of the age groups for which it is intended. Each

AMERICAN JOURNAL OF PUBLIC HEALTH

chapter is introduced by questions which arouse the curiosity and interest of the reader, while at the end of the chapters are test questions and suggestions for simple experiments. The illustrations are exceptionally good and instructive.

C. M. HILLIARD

How Great Cities Are Fed—By W. P. Hedden. Boston: Heath, 1929. 302 pp. Price, \$2.80.

The city dweller who desires a well balanced diet can secure it only if modern commerce makes possible the effective distribution of perishable food-stuffs. A tremendous quantity of such commodities is now transported daily into every large city. How it is done, the facilities needed, the elements of marketing costs, and future developments in this field, are ably discussed in this contribution to the Agricultural Commerce and Administration Series, edited by E. G. Nourse. The book is well printed and illustrated, and should be valuable to all those concerned with agricultural economics.

JAMES A. TOBEY

The Physiology of Oral Hygiene and Recent Research—With Special Reference to Accessory Food Factors and the Incidence of Dental Caries—By J. Sim Wallace, D.Sc., M.D., L.D.S. (2d ed.) London: Baillière, Tindall and Cox, 1929. 228 pp. Price, \$3.50.

The author is one of the most active as well as one of the best known students of oral hygiene in England. He is not considered orthodox in regard to the effect of deficiency in certain vitamins on their formation of the teeth, though one cannot read his evidence without feeling that he has given careful study to the matter, and has strong grounds for his opinions. He pays his respects to the Medical Research Council (English) in no uncertain terms, and believes that it has been responsible for

the pushing of certain supposed vitamin containing preparations at the expense of fresh air, good food, cleanliness, sunlight and exercise, holding that as far as dental hygiene goes, its methods have "demoralized research, obstructed progress and commercialized science."

He believes that caries is brought about chiefly by carbohydrate foods, interference with the natural instinct of infants to gnaw, and depriving children of foods which make them exercise their teeth and jaws. He mentions particularly the "lodgeability, fermentability, viscosity, and impermeability of foods with regard to acids and alkalies," and in view of the findings on examination of many school children endorses the quotation "the better the school the worse the teeth," believing that dental caries is a "luxury disease" rather than a "deficiency disease."

The book is well printed and illustrated.

M. P. RAVENEL

Insects, Ticks, Mites and Venomous Animals of Medical and Veterinary Importance. Part I—Medical—By Walter Scott Patton, M.B., Ch.B. (Edin.), F.E.S., and Alwen M. Evans, D.Sc. Croydon: H. R. Grubb, Ltd., 1929. 785 pp. Price, \$5.50.

The authors have presented in text form the subject matter covered in a course of lectures and laboratory exercises required of students in tropical medicine in the University of Liverpool. The book is a veritable storehouse of knowledge for the layman, the practitioner, and the student of medical entomology. The subject matter is well selected and fully treated, but for the lay reader a table of contents or an index to the different phases of the material presented would make it much more valuable.

All the important groups of arthropods which are vectors of human disease and those which are harmful to

man in other ways are discussed. Special attention is given to the insect carriers of disease.

The illustrations, which include photographs and drawings of unusual quality, are abundant and good, the printing is excellent and very free from errors. To the practitioner the discussions on diagnosis and the nature and cure of the various diseases are especially commendable.

This volume is dedicated to twelve men who have lost their lives while investigating the etiology of diseases transmitted by insects and acari.

L. HASEMAN

The Healthy Mind. Mental Hygiene for Adults—*By Joseph Jastrow, Douglas Thom, James Walsh, Thomas Verner Moore, Karl Bowman, Abraham Myerson, V. V. Anderson, and Esther Loring Richards. Edited by Henry Elkind. New York: Greenberg, 1929. 269 pp. Price, \$3.50.*

Expert in psychiatry, and with an unusual flair for its popular presentation, seven eminent physicians and one psychologist presented a series of lectures on keeping mentally fit before a Boston audience during 1929. The result, as is inevitable nowadays, was a book. Like all such results, the book is uneven in style, unsystematic in arrangement, and inconsistent in statement, though never crudely or excessively so.

Even if it does exhibit these defects, the book is also interesting, informative, and indubitably of value. Much of the range of mental hygiene is ably and acceptably presented. Dr. Thom contributes the opening essay, which soon becomes interesting and practical in telling how the mental hygiene of childhood affects adult behavior. Dr. Walsh wanders and rambles, though always entertainingly, with an ardent plea for more leisure in American life; while later in the book Dr. Anderson puts in

a good word for more and better work. Dr. Bowman has a practical and simple essay on fatigue, worry, and depression; but Dr. Moore's dissertation on emotion and intellect is occasionally far from simple, though sufficiently practical. Even a Boston audience might stumble over "the positive normal values of the affective states in cognitive experience."

"Nerves" are acceptably dealt with in this interesting symposium by Dr. Richards, the only representative of her sex among the authors. She boldly points out some of the many flaws in medical practice with respect to psychiatric attention to patients. Perhaps the most notable of the essays is that by Dr. Myerson on normal and abnormal fear, even though he decries the extravagance of popular health propaganda. Finally, Dr. Jastrow contributes an admirable summary.

This book is a valuable contribution to one of the most important of modern health problems. Sanitarians can read it and recommend it with profit.

JAMES A. TOBEY

National Conference of Social Work at San Francisco, June, 1929—*Editorial Committee: Bleecker Marquette, Chairman, Porter R. Lee, Jane M. Hoey, Joanna C. Colcord, Howard R. Knight, Editor, Bertha Freeman Hooper, Asst. Editor. University of Chicago Press, 1930. 682 pp. Price, \$3.00.*

It is stated in the foreword that considerations of space, general adaptability, permanent value and previous information printed on the subject have led to the omission or abridgment of certain of the papers. It is distinctly pointed out that the fact that a paper is omitted is not to be interpreted as a reflection upon its value.

Among the papers particularly relating to health is an interesting presentation of "The Progress of Occupational Disease Compensation in California,"

by Will F. French, Director of the California Department of Industrial Relations. On the experience of California, Mr. French presents a strong argument for having workmen's compensation laws cover all occupational diseases. Students of the subject will find this paper valuable.

"Gonorrhea and Syphilis—the Biggest Single Problem in Health, Welfare and Community Programs," is presented by Dr. Thomas Parran, Assistant Surgeon General, U. S. Public Health Service, who discussed the extent of the problem, and by Dr. William F. Snow, who presented the solution to the problem. Both of these well organized papers are contributions to the literature on this subject.

"The Economic Aspect of Medical Care" is discussed by Dr. W. P. Shepard, Assistant Secretary, Welfare Division, Metropolitan Life Insurance Company, San Francisco. This paper shows a splendid grasp of the problem of the high cost of medical care. The importance of paid staffs for clinics and hospitals, the desirability of more comprehensive training for both medical students and social workers, the necessity of conferences between the executives of medical and relief agencies in order that they may better understand each other's work, are well emphasized. As an illustration of this type of coördination the work of the Berkeley Coördinating Council is described. Limitation of intake and the adoption of the appointment system by clinics, the reviewer considers to be indispensable. "The Cost of Public Health and Medical Care" is presented by Bleeker Marquette, Executive Secretary of the Public Health Federation, Cincinnati.

In "The Tuberculous Migrant, A Family Problem," Miss Jessamine Whitney, statistician, National Tuberculosis Association, sets forth an excellent body of fact material on the magnitude of this problem which she states is particularly acute in the Southwest.

A scintillating and instructive paper is given by Virginia R. Wing, Director of Health Education of the Cleveland Health Council, in which she discusses a number of psychological experiments in health publicity. The material is new, interesting and well arranged.

The four papers on mental hygiene are all constructive and merit careful reading. BLEECKER MARQUETTE

Control of Endemic Diseases in the Netherlands Indies—*Edited by the Netherlands Indies Medical and Sanitary Service. Landsdrukkerij, 1929. Weltevreden. 77 pp.*

Here we have an extremely interesting report by the Medical and Sanitary Service of the Netherlands Indies. The two longest chapters in the report are devoted to malaria and plague. The anopheles which is dreaded in that part of the world is the *A. ludlowi*.

The report is well written in excellent English, and is abundantly illustrated with pictures of before and after; i.e., before the drainage of fish ponds and the introduction of sanitary methods, and after. It constitutes a preachment of the utmost value demonstrating man's control over tropical diseases. The whole report is full of meat.

M. P. RAVENEL

The Alien in Our Midst—*Edited by Madison Grant and Charles Stewart Davison. New York: Galton Publishing Co., 1930. 238 pp. Price, \$3.00.*

This is a collection of brief essays and excerpts from the writings of various more or less noted persons who have said their say on one side of the immigration question. The book is a tract in support of restriction of immigration and as such is an able partisan presentation. It deals with sociological, economic, and eugenic problems rather than with public health.

JAMES A. TOBEY

The Epidemiology and Control of Malaria in Palestine—By Israel J. Kligler, *Hebrew University, Jerusalem*. Chicago: University of Chicago Press, 1930. 240 pp. Price, \$5.00.

This book gives a description of the work carried out under the Hadassah Medical Organization which was fostered and supported by Justice Louis D. Brandeis and Bernard Flexner.

It is extremely interesting, and in many ways the fate of the Jews who settled in the areas described is a repetition of what took place in Ancient Greece and Italy. Malaria has practically wiped out of existence a number of the settlements.

The chief points in the campaign were: (1) detection and treatment of carriers, (2) antimosquito campaign, and (3) education. Important observations on the action of quinine on the malarial parasite are recorded. The author considers quinine prophylaxis as unsuccessful, many cases appearing even among those who were thoroughly quinized, many others developing from 2 to 3 weeks after its suspension. In other cases it maintained a latent infection. He considers the prophylactic administration of quinine as really a method of abortive treatment.

The book is well illustrated and contains numerous charts and tables which form the basis of the author's conclusions. It is beautifully printed, and is a valuable contribution to the study of malaria in the world.

M. P. RAVENEL

Laboratory Testing of Germicides and Chemo-Therapeutic Agents—By Otto Schöbl. (*Published in reprint form.*) *Philippine J. Science*, 40, 2: 283 (Oct.), 1929.

Testing of Germicides. A critical review of the value of laboratory tests of germicides as related to clinical value is given. In this connection, the results obtained by Reddish and Drake on the

value of mercurochrome and tincture of iodine for preoperative skin disinfection are criticised because only one test organism, *Staphylococcus aureus*, was used. Similar work by Simmons is commended because he used six test organisms, only two of which, however, are of any practical significance from the standpoint of preoperative skin disinfection. The author overlooks the fact that by using only *Staphylococcus aureus*, the most common cause of post-operative infection and the most resistant of the pyogenic organisms, Reddish and Drake were able to repeat their work more often and with greater accuracy, for which reason their results are just as valuable, if not more so, than those published by Simmons.

G. F. REDDISH

Lehrbuch der Protozoenkunde, eine Darstellung der Naturgeschichte der Protozoen mit besonderer Berücksichtigung der parasitischen und pathogenen Formen—Begründet von Franz Doflein, neubearbeitet von Eduard Reichenow (ed. 5). Jena, Verlag von Gustav Fischer. 1262 pp. 1201 figs. 1927–1929. Price, 64 marks unbound, 70 marks bound.

Clinical technicians, bacteriologists, pathologists, and protozoologists alike will welcome this long delayed 5th edition of Doflein's textbook of Protozoology. Its great value lies in its comprehensiveness and its wealth of splendid illustrations. The specialist who is concerned merely with the Protozoa as related to disease needs this broader background to see this wonderfully diversified and widely adapted group of animals in their true places in nature. This new edition is very largely rewritten, due to recent additions to the field. The reviser, Professor Reichenow, in the Hamburg Institute for Tropical Diseases, has somewhat expanded the proportion of

space devoted to the parasitic species and genera of Protozoa. For the first time in this edition, the spirochetes are omitted, since opinion among protozoologists is all but unanimous that they do not belong in the Protozoa.

The accounts of amebic dysentery, the malarias, leishmaniasis, parasitic flagellates, and of the Sporozoa are well illustrated and represent current German opinion in these active fields of research. No clinical laboratory should be without this encyclopedic work of reference.

CHARLES A. KOFOID

Lead Poisoning—*Report of the Committee on Lead Poisoning, presented to the Industrial Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minnesota, October 4, 1929. New York: American Public Health Association, 1930. 37 pp. Price, \$75.*

The material in this report is intended to be used either directly or indirectly by the general practitioner, the industrial physician, the safety engineer, and Workmen's Compensation Commissions.

Most of the material is segregated into three parts, which provide standards for diagnosis, individual treatment, and industrial control. A short bibliographic note, summarizing the types and describing the kinds of material used, is also included.

Under Standards of Diagnosis are included definitions of the various terms used, with a discussion of these definitions. The symptomatology of acute lead poisoning and of chronic lead poisoning is described.

Treatment is suggested for immediate toxic manifestations, and also that which is directed for the removal of lead accumulated in the tissues.

Under the heading of Standards of Industrial Control, specific suggestions

are given for the hygiene of work-places, for personal hygiene, and for medical supervision.

The committee "has endeavored to emphasize those general principles which seem best to have met the test of practical experience."

This report is a valuable contribution to our knowledge of lead poisoning, and should be in the hands of all physicians, safety engineers, and workmen's compensation officials. C. O. SAPPINGTON

Diagnostica e Tecnica di Laboratorio. *Rivista Mensile—Vol. I, No. I. Naples: Piazza S. Domenico Maggiore. Price (Foreign), 150 Lira.*

A monthly review of the scientific literature of the world in the Italian language has been launched under the guidance of Luigi d'Amato and E. Luigi Zoja with the assistance of a considerable number of scientists among whom one finds Hawk, Mathews, Kahn, Kilduffe and Wells representing this country. Other well known sponsors include MacLeod, Lattes, Castellani, Levaditi, Meinike, Ascoli and Izar. The work seems to be another *Biological Abstracts* although more strictly limited to medical biology. It covers pathology, bacteriology and hygiene, physiology and physiological chemistry, clinical medicine, pediatrics and allied sciences in so far as the laboratory side of these sciences is concerned.

The initial number contains a statement of purposes, an invitation to foreign readers to collaborate in abstracting, several original contributions, editorials, notes and news, and 52 pages of abstracts. Whether such a journal is needed at this time remains to be demonstrated. The difficulties imposed by the language and the fact that in this country abstract journals rather thoroughly cover the field causes one to suspect that it will have only limited circulation.

N. W. LARKUM

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Washington, D. C.—The annual report of the health officer for the fiscal year ended June 30, 1929, is primarily noteworthy for the valuable statistical tables covering a long period of years. The general mortality rate for the calendar year 1928 was 12.9, the rate for whites being 10.5 as compared with the rate of 21.6 for the colored. An average infant mortality rate of 64.6 was recorded; white 45.3, colored 107.4. The birth rate for white persons has shown a steady decline to 15.1 in 1928 as compared with 24 for the colored.

The tuberculosis death rate has shown a gradual decline among white persons, and the rate is about one-fifth that of the colored rate; 58.9 white, 256.3 colored, as compared with a rate of 102.9 for the white and 356.4 for the colored in 1917. One of the features of the tuberculosis clinic for both adults and children is the X-ray work. The Health Department has maintained a free X-ray clinic service under expert direction since 1918, during which time thousands of X-ray pictures have been taken for the guidance of clinicians. In 1929, 1,325 such pictures were taken for adults and 1,236 for children. During the year the Tuberculosis Association of the District of Columbia, a nonofficial organization, undertook a campaign to round up young children who had been known to be exposed to the infection of tuberculosis for the purpose of having them physically examined. This work was carried out under the auspices of the Tuberculosis Association with the coöperation of the Health Department. The tuberculosis contact clinic was in the same building as the adult tuberculosis clinic of the Health Department, and the records used were similar to those of the Health Department.

At the close of the year 1,406 dairy

farms shipping milk and cream into the District of Columbia were registered. The number of cattle on these farms was 28,425. The farms were inspected on an average of 5 times during the year. For 25 years the Health Department has made systematic use of the official dairy farm score card. The value of the methods employed is effectively illustrated by photographs of actual conditions on the dairy farms and in the milk plants arranged in the form of an effective exhibit in the Health Department office.

Territory of Hawaii—A comprehensive report of the Territorial Board of Health, covering 246 pages, contains interesting photographs, illustrating an intensive toxin-antitoxin immunization campaign, many valuable statistical tables, charts and maps, as well as a detailed financial statement. This Territory, with an estimated population of 357,649, records a birth rate of 32.5, a death rate of 16.5, and an infant mortality rate of 101.7. Reference is made to an undue prevalence of meningitis during the year, following the arrival of a steamer from the Orient on September 26, 1928. The peak was reached during the month of March when 68 cases were reported, of which 64 were among passengers of arriving vessels, including 2 from Army transports. During the year there were 198 cases with 68 deaths reported for this disease.

Through the coöperation of the Honolulu Chamber of Commerce and private agencies, funds were obtained to augment the limited appropriation of the Board of Health in the inauguration of a toxin-antitoxin immunization campaign. This campaign was successfully carried out through the coöperation of practicing physicians, government phy-

sicians, public health nurses, parent-teacher associations, the Free Kindergarten Association, Palama Settlement, and the principals and teachers of public and private schools. The results of this campaign are tabulated in detail in the report. In Honolulu alone, with a population of 113,000, 11,222 school children and 2,771 kindergarten children were immunized. On the Island of Hawaii, with a population of 82,134, 14,965 children of all ages were immunized. This is undoubtedly one of the most successful diphtheria immunization campaigns carried out during the past year.

A careful analysis is made of infant mortality according to districts in the various islands making up the Territory of Hawaii. There were conducted 1,260 child health conferences, with a total attendance of 22,308 children ranging from 3 weeks to 6 years of age. There were established 6 new health centers in the Territory during the year. One of the outstanding events in the public health nursing field was a series of 2 courses of 6 weeks each given to the nurses by the University of Hawaii Extension Division on Methods of Case Work. Space does not permit a more detailed review of interesting data recorded in this report.

The Commonwealth Fund—Devoting the major part of its income to activities in the fields of public health, preventive medicine, and mental hygiene, and to the enrichment of British-American relations, the Commonwealth Fund, according to its eleventh annual report, made appropriations totalling \$2,028,759 during the year ending last September 30. Among the year's developments were the opening of two new rural hospitals and the adoption of a new public health program in this country; the establishment of a child guidance clinic in London; and the completion of the Fund's child health program in Austria—the 6 years of co-

operative effort resulting in the cordial acceptance by the Austrian Government of responsibility for continuing practically all the activities conducted during that period. The last of a series of 4 child health demonstrations in the United States was within a few months of completion as the year ended.

Fellowships for graduates of British universities to study in America were increased from 25 to 35, of which 5 were open to students from the Dominions. A new group of 3 fellowships, which, like the original fellowships, are for 2 years each, was created for men of British descent who hold appointments in the British Government service overseas.

In the Fund's mental hygiene activities the year has been one of consolidation and technical progress. The Institute for Child Guidance, maintained by the Fund in New York City, received an increased number of children for treatment and enlarged its quota of students for professional training. The National Committee for Mental Hygiene was enabled to continue, through its Division on Community Clinics, advisory service to communities wishing to begin child guidance work and to establish clinics. Provision was similarly made for continuance of the service of the National Committee on Visiting Teachers, in promoting professional training in that field, presenting the elements of visiting teacher work to teachers and school administrators, carrying on a limited number of demonstrations, and giving counsel to interested communities.

With the opening of 2 new hospitals and the continued work of 2 previously established, 4 rural districts, 1 each in Tennessee, Virginia, Maine, and Kentucky, are now provided with general hospitals of their own, as a result of the Fund's activities. Additional hospitals have been opened in 2 more districts, in Kansas and Ohio, since the close of the

year covered by the report. It is estimated that through this program some 410,000 people are enabled to enjoy—near at home—the safety and convenience of hospital service which in former years they had to seek at a distance or forego altogether. The objectives of this program are far wider, however, than the provision of these facilities, for these constitute only the central part of a general attempt to raise the level of rural health through stimulating the medical profession and the public in the localities to develop practicable public health services suitably linked with the hospitals, and to foster an intelligent interest in preventive medicine.

The new public health program, with 1930 as its first year, will draw upon the experience both of the child health demonstrations and of the rural hospitals, but will provide a fresh approach to rural health problems. In an effort to encourage the development of both public health and general medical service in rural communities, specific contributions to professional education will be set up in each of two or three states. The projects, to be initiated and administered by the state health departments, will include the formation of a field staff to build up local health organizations and the establishment of well rounded health units in two selected districts. The educational projects will include the strengthening of the medical schools which chiefly train doctors for service in the selected states, scholarships or loan funds for students of medicine who intend to enter rural practice, and fellowships for rural physicians who wish to improve their grasp of the best current technic.

Among the special grants made by the Fund were several to be applied to medical research—for example, the study of the causes and treatment of cardiac trouble in children, at Johns Hopkins; a study of serums and vaccines significant for the control of car-

diac disorders, at Cornell University; the research work of the Heart Committee of the New York Tuberculosis and Health Association; an investigation at the University of Michigan looking toward the development of a blood test for tuberculosis; the study of epilepsy and multiple sclerosis at the New York Neurological Institute; and continued work on serum treatment for the pneumonias by William H. Park, M.D.

A grant of \$50,000 was made to the Notre Dame Bay Memorial Hospital, at Twillingate, Newfoundland, supplementing previous grants to this hospital, the only one in 300 miles of seacoast. The institution serves 50,000 people, mostly fishermen and their families, and has been successful in enlisting their confidence and support. The local community has already contributed more than \$80,000, besides much free labor. On one occasion 600 men gave 2 days' work to move a frame building three miles over snow and ice to provide a nurses' home.

San Jose, Calif.—Photographs and organization and statistical charts feature this 1929 report. This city, with an estimated population of 62,750, reports a birth rate of 13.8 and a death rate of 10.7, the average age at death being 53.8 years. A resident infant mortality rate of 44.4 is a gratifying record. The percentage of hospital births for the year was 70. Scarlet fever heads the list of communicable diseases with 351 cases and 1 death, but the low mortality indicates a mild form of the disease. There were 121 cases of whooping cough with 4 deaths and 49 cases of diphtheria with 2 deaths. A decrease was noted in the incidence of diphtheria among school children and the health officer attributes this change to the immunization work done in the schools. A financial statement indicates an expenditure for the year by the Health Department of \$19,363.

Greenville, S. C.—In the 1929 report the Board of Health makes a plea for more nurses for infant, prenatal and school work, and also for a meat and milk inspector. The estimated population for 1929 was 33,000 with a death rate of 10.6, a decrease over 1928 death rate of 15.5, a birth rate of 18.4 showing a slight increase over 1928. The infant mortality rate was 82.1, 71.1 for white and 107.1 for colored persons. The routine school examinations have been discontinued owing to the lack of personnel, but a nutrition worker assists the city schools and examines and aids undernourished children. A school den-

tist is still maintained. A baby and a prenatal clinic are held once a week for indigents, in connection with the city hospital—other clinics are the biological clinics held every day; orthopedic clinics, once a week; a mental hygiene clinic, once a week; and a tuberculosis clinic, one day for whites and another for colored.

A new water supply, at a cost of \$2,000,000, has been provided and \$1,500 has been appropriated for mosquito control. The important causes of death are heart disease with 134 deaths; tuberculosis with 40; and pneumonia with 28 deaths.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Fertility of Native White Women—This summary of a paper appearing elsewhere points briefly to the conclusion that the rates of the least fertile rural class are higher than the most fertile urban class, and in both there is a definite inverse relation between fertility and social status.

ANON. Fertility of Native White Married Women in Various Social Classes as Shown by the Census Returns for 1910. *Quarterly Bull. (Milbank Memorial)*, 8, 2 (Apr.), 1930.

College Student Health—The physical condition in which students come to college is an interesting commentary on the hygienic ideas and practices in our better class homes. Five years' findings are recorded.

BEARD, J. H. Health in College Students. *Illinois Health Quarterly*, 2, 1: 21 (Jan.-Mar.), 1930.

Nursing for British Insurance Policy Holders—Steps leading to the formation of a Central Bureau of Industrial Nursing are recounted. The experience in American insurance company nursing was studied, followed, and then a method of consolidation effected.

CHARLEY, I. H. Nursing and Insurance in Great Britain. *Pub. Health Nurse*, 22, 4: 177 (Apr.), 1930.

Federal Mental Hygiene Activities—The activities of the U. S. Public Health Service in the field of mental hygiene are enumerated. The extent of these activities is little appreciated by most of us.

CUMMING, H. S. Mental Disorders and the Public Health. *Pub. Health Rep.*, 45, 14: 726 (Apr. 4), 1930.

Diphtheria Prevention—Had the diphtheria case and death rates prior to

the immunization campaign continued since, 237 cases and 11 deaths would have occurred in Brookline (Mass.). This saving at a cost of \$4,010 makes a satisfactory showing.

DENNY, F. P. Diphtheria Prevention in Brookline. *New Eng. J. Med.*, 202, 15: 716 (Apr. 10), 1930.

Tuberculosis Rates—Uncomfortable statistics for the "viewers-with-alarm" who have distressed themselves over the hygienic life of the flapper. An excellent analysis of New York City tuberculosis death rates by age, sex and color.

DROLET, G. J. Epidemiology of Tuberculosis in New York City. *J. Prev. Med.*, 4, 2: 115 (Mar.), 1930.

Uses of Census Tracts—Do you know what a census tract is? How Cleveland obtained its census tracts and what it is doing with them is a story which will interest the sanitarians who suppose that tracts have to do only with prohibition or morals.

GREEN, H. W. Facts, Figures and Fiction in Social and Health Statistics. *New Eng. J. Med.*, 202, 16: 771 (Apr. 17), 1930.

Differentiation of the Streptococci—Studies of the hemolytic streptococci are reviewed and lead the author to conclude that erysipelas and scarlet fever are as distinct etiologically as they are clinically.

HEKTOEN, L. Advances in the Study of Streptococci. *J. Bact.*, 19, 2: 57 (Feb.), 1930.

Who Gets Diphtheria?—Over 90 per cent of 703 (New Jersey) cases occurred among unprotected children. Of the 65 "immunized" persons reported, 20 had not completed treat-

ments, 13 became sick within 3 months of immunization. Only 5 of the remaining 32 had a subsequent Schick test. Of these 1 was positive, 1 not recorded, leaving only 3 who had had a known negative Schick reaction.

EAKINS, W. T. Who Gets Diphtheria Now-a-Days? *Pub. Health News* (New Jersey), 15, 4: 68 (Mar.), 1930.

Psittacosis in England—This is a detailed account of the disease of parrots replete with historical references and case studies of real interest to persons concerned with this baffling disease.

HUTCHINSON, R., *et al.* A Study of Psittacosis. *Brit. M. J.*, 3613: 633 (Apr. 5), 1930.

Chlorin as a Milk Preservative—Is there danger that farmers might use chlorin washing compounds as milk preservatives? Experimentally, chlorin was found inferior to formaldehyde, and hence not likely to be used illegally.

JOHNS, C. K. The Preservative Effect of Chlorin Compounds in Milk. *Canad. Pub. Health J.*, 21, 4: 162 (Apr.), 1930.

Progress in Cancer Control—Encouraging indeed is the report of the activities of the State Department's (Massachusetts) Division of Adult Hygiene. Who came to the state aided cancer clinics, in what condition and why they came is the most interesting part of the story.

LOMBARD, H. L. Annual Report of the Division of Adult Hygiene of the Massachusetts Department of Public Health. *New Eng. J. Med.*, 202, 15: 719 (Apr. 10), 1930.

Canadian Health Administration—This dissertation on full-time health organizations for Canada is an interesting supplement to our own efforts in the same direction.

McINTOSH, J. W. A Dominion Medical Service. *Canad. Pub. Health J.*, 21, 4: 177 (Apr.), 1930.

Diet and Health—Experimental and clinical evidences are presented to show

the importance of diet in relation to health and disease. A useful review of scientific opinion abroad.

MELLANBY, E. The Relation of Diet to Health and Disease. *Brit. M. J.*, 3614: 677 (Apr. 12), 1930.

An English Opinion of Pasteurization—Nature never meant milk to be heated. Pasteurization gives false sense of security; kills natural bactericidal substances in milk; does not always kill tubercle bacillus. Pasteurized microorganisms and manure cannot be good for babies. These are only a few of the specious arguments in a paper extolling raw milk.

MENTON, J. Bovine Tuberculosis in Relation to the Public Milk Supply. *Med. Off.*, 43, 14: 153 (Apr. 5), 1930.

School Child Health—Here is a truly stimulating paper; witness the following: "The school is an educational institution, not one of relief. . . . No free diphtheria immunization has been offered except to indigents. . . . The objective of school medical inspection should be the periodic examination on parental responsibility." Read it.

MOORE, F. Responsibilities of the Medical Profession in Health Program in Public Schools. *J. A. M. A.*, 94, 15: 1109 (Apr. 12), 1930.

Rural Prenatal Program—How to win the confidence of expectant mothers in a southern rural community where the "open spaces" are really great, is the theme of this interesting story.

PAGE, F. E. Prenatal Program in Franklin County, Ala. *Pub. Health Nurse*, 22, 4: 180 (Apr.), 1930.

New York State Diphtheria Prevention—What became of the slogan about no diphtheria after 1930? What was attempted in diphtheria control in New York is the burden of this excellent report. It seems that some diphtheria may be anticipated after 1930 despite

many worth while projects for which all due credit should be accorded.

SEFTNER, H. F. A Report on the Progress of the Upstate Diphtheria Prevention Campaign to Date. *New York State J. Med.*, 30, 6: 331 (Mar. 15), 1930.

More about Toxoid—Administered in three doses, 0.5, 1.0, and 1.5 c.c., 3 and 2 weeks apart, toxoid treatment resulted in producing a negative Schick test in 96–100 per cent of the cases Schick positive before immunization. The toxin-antitoxin proponents die hard.

RAMON, G., and HELLE, G. I. Anatoxin as an Immunizing Agent against Diphtheria. *Am. J. Dis. Child.*, 30, 4: 686 (Apr.), 1930.

Whooping Cough Prophylaxis—A Milwaukee children's home experienced an increased incidence of whooping cough despite prophylactic vaccination with *B. pertussis*. Both the institution and the city enjoyed a lower mortality.

SCHOWALTER, R. P. The Value of Vaccine in the Prevention of Whooping Cough. *Am. J. Dis. Child.*, 39, 3: 544 (Mar.), 1930.

Diphtheria Immunization—Another report of the superiority of toxoid over toxin-antitoxin as the agent of choice in the immunization of the preschool child against diphtheria.

SCHWARTZ, A. B., and JANNEY, F. R. The Comparative Value of Toxoid and Other Agents in the Immunization of the Preschool Child against Diphtheria. *Am. J. Dis. Child.*, 39, 3: 504 (Mar.), 1930.

Control of Syphilis—After discussing the potentialities in our largely ineffectual attempts to prevent the continued spread of syphilis, this author

proceeds to discuss treatment in its epidemiologic aspects. An excellent paper.

STOKES, J. H. Critical Treatment Problems in Syphilology. *J. A. M. A.*, 94, 14: 1029 (Apr. 5), 1930.

Commercial Health Propaganda—Not entirely disinterested is most of the recently awakened commercial activity in health promotion. Yet the results are good and are welcomed by health workers, says the writer.

TOBEY, J. A. Business Discovers Health. *Technology Rev.*, 32, 5: 2 (Mar.), 1930.

Smoke Abatement and Ultra-Violet Light—It appears that a complete return of the "health-giving rays of the sun" may not follow close upon the enforcement of smoke abatement measures applicable to existing combustion processes. The study was made in Chicago.

TONNEY, F. O., *et al.* Loss of Actinic Intensity in Urban Sunshine Due to Air Pollution. *J. Prev. Med.*, 4, 2: 139 (Mar.), 1930.

Differentiating Streptococci—Chocolate agar is suggested as a culture medium upon which the pathogenic streptococci may be differentiated.

TUNNICLIFF, R. Streptococci from Scarlet Fever, Erysipelas and Septic Sore Throat. *J. A. M. A.*, 94, 16: 1213 (Apr. 19), 1930.

Preventorium Treatment and After-Care—What happens to the children who go to their homes after an instructive period in a preventorium? This study by a Syracuse institution points to the great importance of adequate follow-up.

WISEMAN, J. R. Malnutrition. *Am. J. Dis. Child.*, 39, 4: 758 (Apr.), 1930.

NEWS FROM THE FIELD

TOKIO'S HOSPITAL

THE cornerstone of the Medical Center of St. Luke's International Hospital at Tokio, Japan, was laid on March 28. Much progress has been made on this new center, which has been described as an important factor in cementing friendship between Japan and the United States.

This institution has the support of the Japanese Government, although it is an American church institution, and the Emperor of Japan has contributed \$20,000 toward the fund for its construction.

This new center replaces the hospital which the earthquake of 1923 destroyed.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

THE Fourth Public Health Institute for health officers and other public health workers will be held at the Massachusetts Institute of Technology from June 23 to July 12, 1930.

This Institute aims to provide for the health officer or other qualified public health worker an opportunity to study public health procedures and to examine modern public health practice under the direction of experts in the respective fields.

There will be lectures, round table discussions, conferences and numerous laboratory or clinical demonstrations or field trips.

MENTAL HYGIENE IN ARGENTINA

ARGENTINA has recently evidenced recognition of the importance of mental hygiene by organizing a league of mental hygiene to study methods for the prevention of mental disorders and improvement in the treatment of mental patients. The league

will work for the application of mental hygiene principles in schools, industrial establishments, and elsewhere; organize mental hygiene conferences; and try to enlist the coöperation of the public authorities.

VIENNA'S "MUTTERSCHULEN"

THE city of Vienna, Austria, has started schools for mothers in which they are taught about nutrition and nutritional disturbances, infectious diseases and protective inoculation, care of the new-born, and of well and sick children, mental hygiene of children, and the hygiene of sleep. Lessons on children's songs and games and the making of children's clothing may be added. The courses are under the direction of a woman physician and a woman welfare worker.

COLORADO POST-GRADUATE COURSE IN PSYCHIATRY

A POST-GRADUATE course in neuropsychiatry is to be given at the Colorado Psychopathic Hospital, Denver, under the auspices of the University of Colorado School of Medicine and Hospitals beginning July 1 and ending July 31, 1930. The course is for physicians only and will include material on mental hygiene, the psychopathology of childhood, clinical psychiatry and neurology, mental testing, internal medicine, neuropathology, serology, biochemistry and roentgenology. The fee for the course will be \$125, and registration begins June 30.

DR. HERMAN ADLER GOES TO CALIFORNIA

DR. HERMAN M. ADLER, Illinois state criminologist and director of the Juvenile Psychopathic Institute, has

accepted a professorship of psychiatry at the University of California, Berkeley, and an appointment as consultant to the California State Department of Institutions. Dr. Adler, who was assistant professor of psychiatry at Harvard University Medical School, went to Chicago in 1916 to study the facilities in Cook County for the detection and care of mental diseases, under the auspices of the Rockefeller Foundation and the National Committee for Mental Hygiene. His assistant for several years, Dr. Paul L. Schroeder, has been designated by the governor to succeed him.

FLORIDA SHORT COURSES IN WATER AND SEWAGE TREATMENT

THE Fourth Annual Meeting of the Florida Section, American Water Works Association, was held in Gainesville, Fla., on April 10 and 11. It was preceded by the first Short Course in Water and Sewage Treatment offered by the General Extension Division of the University of Florida, in conjunction with the Florida Section, American Water Works Association, and the Florida State Board of Health, on April 8 and 9. Enrollment for the Short Course considerably exceeded the expectations, 69 having registered during the 2 days in which it was given. Conforming with the request of the Association the Short Course will be made an annual affair, and the time will be extended to 4 or 5 days, thus permitting a more thorough treatment of the subjects discussed.

The registration for the Fourth Annual Meeting was the largest in the history of the section, about 125 being in attendance. During the 2-day session, 19 papers were presented and discussed.

SAFETY BROADCASTING

THE Third Series of National Broadcasts under the auspices of the National Safety Council opened April 25 with an address by Irving Fisher of

Yale University. The 13-week program, given on successive Friday evenings from 7:15 to 7:30, alternates timely safety discussions by noted men and women with safety playlets. The programs are given on eastern daylight saving schedules.

This is the third national network devoted to safety problems during the past year and a half. Twenty National Broadcasting stations, headed by WEAf, New York, are participating.

W. B. WHITE TO HEAD U. S. FOOD CONTROL OFFICE

DR. Ward B. White, director of the New York State Bureau of Chemistry, has accepted the position of chief of food control, Food and Drug Administration, U. S. Department of Agriculture, effective June 2. This appointment is to fill the vacancy caused by the death of Dr. R. W. Balcom.

Dr. White in his new duties will supervise and direct the scientific and technical work necessary in enforcing the Tea Act, the Import Milk Act, and the Federal Food and Drugs Act as applied to foods.

NEW YORK STATE PUBLIC HEALTH COMMISSION

ANNOUNCEMENT has been made of the appointment by Governor Roosevelt of a Special Health Commission to study and report upon the working of the public health law and the various state and local authorities dealing with the promotion of health. Dr. Livingston Farrand has been asked to serve as chairman of the Commission, which consists of 15 members.

In making the announcement, the Governor issued this significant statement:

As an agency for serving the needs of the people, government should not be a static force but should evolve to meet the changing and developing body of knowledge. This is particularly true in the field of public health in which, during the past decade or two, far-

reaching development of the scientific facts upon which governmental action is based makes particularly necessary a periodic examination of the extent to which the state is meeting the needs of the people in this vital field.

HARD OF HEARING CONFERENCE

THE American Federation of Organizations for the Hard of Hearing will hold its 11th Annual Meeting June 16-19 in New York, as guest of the pioneer organization in this field of social work, The New York League for the Hard of Hearing.

Twenty years ago this group of persons handicapped by impaired hearing organized themselves to study and solve their own problems. Their effort has developed into an international federation comprising nearly 100 organizations in the United States and Canada, carrying on a vigorous campaign of public education in aural hygiene, conservation of hearing, and proper educational and vocational provision for the child with impaired hearing.

Many outstanding scientific, medical and educational leaders are active members of the American Federation, and it is well represented on the White House Conference for Child Health and Protection. It was founded by Wendell C. Phillips, M.D., past president of the American Medical Association, and its president is Harvey Fletcher, Ph.D., also president of the American Acoustical Society. The conference meetings will be audible to hard of hearing persons through a remarkable invention of the Bell Telephone Laboratories.

SOUTHERN SOCIAL HYGIENE INSTITUTE

THE Southern States Regional Conference and Social Hygiene Institute were held in New Orleans, May 23-27, under the auspices of the Louisiana State Board of Health and the New Orleans Council of Social Agencies.

Among the speakers were Dr. Lloyd Thompson, Father Alphonse Schwitalla,

Dr. O. C. Wenger, Dr. James R. McCord, Dr. E. L. Swan, Dr. Walter Clarke, Edna Moore and Henrietta Additon.

NEW LABORATORY CAR

DR. J. C. GEIGER, Associate Professor of Epidemiology in the Medical Department of the University of California, and Epidemiologist of the Southern Pacific Railroad, accompanied by Mrs. Geiger, has been making a tour in the New Laboratory Car of the Southern Pacific Railroad appropriately named "Better Health." In the car he has attended the State Medical meeting at Phoenix and Tucson, Arizona, and the California State Medical Society meeting at Del Monte. We hope to give a description of this car in an early issue, with some details of the uses to which it is put.

MISSOURI PUBLIC HEALTH ASSOCIATION

THE following officers were elected at the general business session of the sixth annual meeting of the Missouri Public Health Association at Jefferson City on April 24:

President, Irl Brown Krause, State Board of Health, Jefferson City, Mo.; First Vice President, Anne Heisler, School of Public Health Nursing, Washington University, St. Louis, Mo.; Second Vice President, Dr. R. C. Haynes, County Health Officer, Marshall, Mo.; Secretary, Pearl McIver, Division of Public Health Nursing, State Board of Health of Missouri, Jefferson City, Mo.; Treasurer, Dr. John W. Williams, Jr., County Health Officer, Springfield, Mo.; Representative on the Governing Council of the American Public Health Association, R. L. Laybourn.

The Association went on record as endorsing the resolution passed by the West Virginia Public Health Association which recommended to the A. P. H. A. that a publication be provided which

would make available the papers presented at the meetings of various state health associations to all members of affiliated societies.

PERSONALS

DR. WILLIAM G. HARRISON, Birmingham, Ala., was chosen president of the Alabama State Medical Association on April 18.

DR. JAMES N. BAKER was appointed State Health Officer of Alabama to take the place of Dr. Samuel W. Welch who died.

DR. FREDERIC W. SCHLUTZ has been appointed head of the department of pediatrics at the University of Chicago's south side clinics. He will also be director of the Bobs Roberts Memorial Hospital for Children, open about May 1.

DR. RALPH G. BEACHLEY has been appointed full-time health officer for Kent County, Md., with headquarters at Chestertown.

DR. ALONZO R. KEIFFER was given a bronze plaque on April 22, to celebrate his fiftieth year in the practice of medicine.

DR. H. L. SAYLER has been appointed City Health Officer of Des Moines, Ia., to succeed Dr. A. J. Lieber. Prior to Dr. Lieber's appointment, Dr. Sayler was Health Officer of this city for about 15 years.

CONFERENCES

June 3-4, New Mexico Public Health Association, Albuquerque, N. M.

June 6-14, National Conference of Social Work, Boston, Mass.

June 9-14, Biennial Convention of the Three National Nursing Organizations, Milwaukee, Wis.

June 12-14, Western Branch of American Public Health Association, Salt Lake City, Utah

June 18-19, State and Provincial Health Authorities of North America, Washington, D. C.

June 20-21, Conference of the Surgeon General, Washington, D. C.

June 23-July 12, Fourth Public Health Institute, M. I. T., Cambridge, Mass.

June 26-27, Pennsylvania Sewage Works Association, State College, Pa.

October 27-30, American Public Health Association, Fort Worth, Tex.

FOREIGN

June 21-28, Royal Sanitary Institute, 41st Congress and Health Exhibition, Margate, England

Aug. 3-9, Second International Congress for Sex Research, London, England

Aug. 4-9, International Veterinary Congress, London, England

Health Aspects of Summer Recreation*

CHARLES F. DALTON, M. D., F. A. P. H. A.

Secretary Vermont Department of Public Health, Burlington, Vt.

THE word "vacation" probably has as many varieties of meaning as there are persons who use it. To some it means two weeks of strenuous work and to others two weeks of doing nothing, with all kinds of variations between these extremes. And this is rightly so on account of the different occupations and different needs of the vacationists. The problem which must confront the individual is the choice of the proper kind of vacation to suit his needs. The problem of the state is to safeguard the places to which the vacationist goes.

THE PROBLEM OF THE INDIVIDUAL

Most people look upon summer vacation as a change from their usual occupation, and some take the need of change so seriously that they overdo the matter and return to their homes not only not refreshed but actually sick. Unfortunately there are no standards by which one can be guided in making suggestions for the use of one's spare time in summer, but a few generalizations may be put down as bearing on the subject. To my mind the case should be governed by common sense, even though the enjoyment may be somewhat curtailed. The health aspect of summer recreation should be the first consideration of the individual in his decision, for here the state cannot help him.

For the sedentary worker who gets little physical exercise in his daily occupation, a sudden round of active tennis, golf, mountain climbing or water sports may be disastrous. On the other hand, a complete change from an active manual employment to a life of sleeping half a day and spending the remainder in a hammock will probably

* Read before the New England Health Institute, Boston, Mass., April 16, 1930.

tie up the body secretions to such an extent that he must resort to cathartics and correctives to maintain even a fairly comfortable existence. An office worker who immediately strips to a bathing suit and spends the day on a sunny beach, or in a boat or canoe, will probably spend the next several weeks treating his skin for sunburn and overcoming the consequent effects of loss of sleep and nervousness.

Dr. Harlow Brooks, in his book on *Angina Pectoris*, says:

The growing habit in America of taking vacations is a step in the right direction, but in many instances some . . . select for their vacation and diversion things which impose more strain than their habitual occupation. The physician will find on any golf course men, the subject of angina or other cardiac disease, who, under the delusion that they are benefiting their health, all untrained and unprepared from a physical standpoint, indulge in stresses and strains fitted for the young college athlete, but not for the mature, and frequently overly plump business or professional man who, six or seven days out of each week, sits at the desk, stands on the turbulent floor of the stock exchange, or under the tremendous stress of the operating room. Old men try to play tennis with their sons, to defeat them at handball, to outdistance them in swimming, to outclimb them in the mountains; many of them develop angina.

These examples are not exceptional nor are they confined to those of the less intelligent classes. The idea of the strenuous life is so much a part of our very existence that we not only work strenuously, but we rest strenuously, and we do everything with a disregard for moderation which in some cases amounts to extravagance. This is what might be called typically American.

The sensible and, therefore, moderate man, especially if he is of the age which is no longer counted among the young, will gradually taper his activity up to the incline from sedentary employment to active recreation, or down from manual labor to healthful rest. He will thus avoid upsetting his bodily functions and end his vacation improved, refreshed and invigorated. He will not try to change from a pale office man to a bronzed athlete in two weeks, nor will he expect a hardened muscular body to perform its function if the stimulation of work is suddenly cut off from his daily routine.

The question of food presents a problem for those who are able to leave home for a trip or vacation. The automobile family starts out with the plan of spending the night, with dinner and breakfast, at some hotel or tourist house, and lunch at some convenient place on the road. The first night, the menu looks inviting with several dishes not usual at home, and a hearty meal is eaten. In the morning instead of the cereal, roll and coffee breakfast on the home plan, the meal may include meats, vegetables and desserts such as would usually constitute a dinner. Lunch may be a sandwich and more coffee or some car-

bonated drink. In the meantime, the call of the road is so urgent that the calls of nature are ignored, or at least not properly attended to. A few days of this régime will turn the happiest family into a nervous, sickly crew, and some time elapses before the family health is regained. A similar story might be told about other forms of vacation. Could these people bring themselves to order their food so as to at least approximate their usual habits, the vacation health problem would be far on the way toward solution. The vacationist of two weeks or less must make use of sound judgment if his recreation is to result in improvement rather than detriment to his health.

To many men the summer is the time of catching up on the exercise which has been neglected during the winter months. The waist line, which has increased from one to three inches as a result of many banquets and much sitting in at bridge, must now be reduced to normal size, and the nerves and digestion which have suffered from similar causes must be repaired. The golf links and a bright spring Sunday give the incentive for a day's outing. At the end of the first nine holes one feels just loosened up and the temptation is great to continue the round once or twice more. The result is too frequently a lame back, sore muscles and a general indisposition to work during the rest of the week, not to mention the strain on the heart which has become flabby from lack of necessity to support such an effort. A gradual course, working up from only nine holes the first day to the more strenuous game later in the summer, is much better than attempting to begin at once where one left off in the fall. A few can stand the sudden exertion; the majority must begin slowly.

THE PROBLEM OF THE STATE

With the summer recreation industry increasing steadily from year to year, the state must assume the responsibility of making every location within its borders safe for vacation purposes. In accepting this added burden, the public health department acts not only in its capacity as guardian of the health of the community, but also as the protector of the good name of the state. This dual responsibility creates one of the situations where public health and economics are so intimately connected that they cannot be separated. The success with which the problem has been attacked is shown by the remarkably small number of communicable diseases contracted in recent years among the hundreds of thousands of tourists and recreation seekers. This is even more remarkable when one considers the unstandardized methods which are applied by the different departments. Efforts are directed toward (1) Sanitation of camping places, (2) supervision of food and water supplies, and (3) control of communicable diseases.

The difficulties connected with camp sanitation are numerous and exceedingly weighty. Being almost exclusively in rural sections, where sewage facilities are not available and water supplies are inadequately protected, every camp represents an individual problem. In Vermont we find it a frequent occurrence that a prospective camp manager buys or leases a beautiful piece of scenery and proceeds to locate his buildings without a thought of sanitation until the actual construction of a sewerage system is begun. Then he finds that the ground is not suitable for sewage disposal or the bathing beach is in danger of pollution or the water supply is liable to contamination. Finally the sanitary engineer of the State Health Department is called in to eliminate the trouble. Septic tank treatment with subsoil disposal will sometimes be effective, but in many camps subsequent chemical treatment of the effluent is necessary. Occasionally, only expert engineering advice and a considerable outlay of money can safeguard the premises.

Leaving out seashore resorts which cannot be considered in this paper, the list includes commercial boys' and girls' camps, adult camps, private camping grounds, municipal camps, tourist overnight camps, roadside eating stands and tourists' lodging houses. With the formidable array of inland recreation places, it is little wonder that the health departments are at a loss to know how to institute methods of control. It is also remarkable that, considering the millions of dollars annually spent at such places, the state legislatures continually fail to provide funds for their proper inspection and supervision. Fortunately the sense of decency which is inherent in most people often saves the day when health departments are powerless.

Various codes of rules have been promulgated for the regulation of summer camps, most of which are good as far as they go, but such rules often fail to take cognizance of the individual problems caused by the variety of conditions to be overcome. It is easy to make a rule that sewage must be disposed of in a sanitary manner, but the camp owner asks how it can be done in his particular location. It is a simple matter of routine to write down that the water supply must be ample and safe, but the spring, well, stream or lake depended upon may require some safeguard or additional source to furnish the proper amount or quality. Sleeping quarters of a certain kind may be called for but frequently the camp is already established, or farm buildings have been already prepared for occupancy.

There is need of personal inspection by persons who are able to report on conditions found, and make recommendations for the best methods of bringing these conditions to a satisfactory level.

DISEASE CONTROL IN CAMPS

Outbreaks of communicable disease in boys' and girls' camps are distressing, both to camp owners and health authorities. The larger camps usually have facilities for isolation and medical or nursing attendance, but some of the smaller ones have no such arrangement. An example of the difficulty in managing such an outbreak occurred in a boys' camp in Vermont recently. Infantile paralysis was diagnosed in 2 boys, both of whom had been in the camp less than two weeks. The camp was made up entirely of tents, with no means of isolation, and in consequence about 100 boys were exposed to the disease. Arrangements were made to remove the patients at once, and an inspection was made of the entire camp population. This resulted in the discovery of 5 more who exhibited suspicious symptoms.

The question then arose as to the best method of handling the remainder. To keep all the boys together meant further exposure for all, and this we were unwilling to do. Finally, after consultation, it was decided to send all the boys to their homes at once. Every boy carried with him a letter to his parents explaining the situation, and at the same time a notification was sent to the State Departments of Health, giving the addresses of all boys within their jurisdiction. The 5 boys with symptoms were kept for several days, but none developed further manifestation, and they were subsequently returned to their homes by automobile with similar notifications. Two of these, however, later developed paralysis while they were being held in quarantine at home.

There was of course some criticism of our action in closing this camp under such circumstances, but I have yet to be informed of any safer procedure which might have been instituted.

At another camp where a resident physician was in attendance and an infirmary was available, 2 polio cases were simply quarantined on the premises and the camp allowed to continue as usual, with no further developments. Cases of measles, mumps and German measles have also been handled in the same way.

THE TYPHOID CARRIER MENACE

With the improvement in the supervision of water supplies, typhoid fever from polluted water is practically unknown. The great typhoid menace is the possible appearance of a typhoid carrier among the food handlers. Some camps make a practice of employing local residents as cooks and waitresses, and where this is done it is always recommended that they select only typhoid-free persons, as far as history and repeated examinations are able to determine. Following the

recent Canadian epidemic of typhoid, much apprehension was felt lest some of the resulting carriers should find employment in the camps. Our department circularized all camp owners and all hotels in the state warning them of the danger and, so far as we know, not a single case occurred from this source of infection.

However, the typhoid carrier is not always within the camp. A few years ago, several cases of typhoid occurred in a large camp of girls, and exhaustive examination of all employees and other possible suspects failed to explain the source of infection. Close inquiry as to the camp routine revealed the fact that on certain days in the week, the girls went to a nearby town, where they bought fruit and confectionery, and following up this clue led to the examination of an Italian fruit dealer, whose place was frequently visited. This man proved to be a carrier and on the elimination of his wares no more cases occurred.

WAYSIDE EATING PLACES

Since the legislatures are largely made up of farmers or those interested in the farm vote, and small lunch places are frequently run in connection with farms, it is practically impossible to secure the passage of regulatory laws governing such places. The plan of securing funds for inspection by means of license fees seems to be working out satisfactorily in some states, but there is yet much to be done before the idea becomes a perfect working model. These places appear over night and in most unexpected locations, and their proper supervision would require many inspectors with restricted territories. The typhoid carrier menace exists as a potential danger at every one, and no amount of sanitary inspection will eliminate it. However, such inspection should be continued, but it should be supplemented by closely following up any cases which occur and by intensive education of the public. Campaigns directed toward wholesale inoculation against typhoid among those who may patronize such stands should also be inaugurated.

OVERNIGHT CAMPS AND LODGING HOUSES

The greater number of automobile tourists divide themselves between tourist rooming houses and the so-called "overnight" camps, which are provided with shacks or cottages of varying degrees of convenience. The competition of cities has resulted in the equipment of many municipal camping grounds, which are either free or may be occupied on payment of a small fee. Most of these are supplied with city water, shower baths and suitable toilet facilities and are generally supervised by the chamber of commerce or the park or street department of the city. They give little trouble to the health department.

The trouble comes from the farmer or rural resident, who happens to have a piece of land on or near the main highway, and suddenly decides that he can draw in a few dollars by opening a camp. A few rough shacks and a dry earth closet complete the equipment and he is ready for business.

Through some twist in human nature, this type of camp is quite largely patronized, particularly by people who start out with the idea of getting back to nature. Frequently one night in such a place is sufficient to disabuse their minds of the idea, but the next day brings others, and the owner's little investment becomes a paying proposition. Meanwhile, however, the camp site is becoming more unsanitary each time it is used and the outhouse more of a menace. Sometimes a stream is available for bathing, and the wash of excreta into this stream is neither seen by the campers nor regarded by the owner. The latter usually feels that he has done his duty if he picks up the papers and tin cans and throws them over the bank.

Of course the state is supposed to supervise all these places and render them safe and sanitary, but only those who have attempted such work realize how much organization would be required to fulfil adequately the expectations of the touring public. So long as there are sufficient numbers to make such a place profitable, there will always be the problem of controlling places of this class. Let us try the fee and license method, as is done in many states. It will probably accomplish something; but unless the health authorities can arrange for very frequent inspection and are furnished with power to forbid the use of unsuitable places, the public must still assume some responsibility if it continues to patronize camps of this type and condition.

A somewhat similar situation exists in regard to tourist rooming houses. Many of the houses available on the road are of the finest type and the accommodations such as would be found in the best of homes. But unfortunately there are others of a different kind, and one cannot always tell from the outside appearance what the inside will be like. Signs showing membership in, and approval by, this or that tourist association may or may not mean anything. Many of these houses are within city limits, some even in populous sections. In licensing these places, it seems that a distinction must be made between the rural and the urban, although they all display the same kind of signs. It is assumed that the cities will supervise the rooming houses within their borders and receive the fees therefrom, while the state assumes responsibility for the rural locations. But, again, it is evident that if these houses are to be kept properly under control, a large corps of inspectors will be required.

WAYSIDE WATER SUPPLIES

The States of Michigan and Pennsylvania have been especially vigilant in inspection of wayside water supplies. These states have used traveling laboratories and plainly marked the safe and unsafe waters. Such outfits are rather too expensive for the New England States to operate unless some coöperative scheme can be devised, which is doubtful. There has been an effort, however, to protect tourists through the organizations which are available, and many such supplies have been marked within this territory. Many warnings have been given against promiscuous use of unknown water supplies, and tourists should by this time know the danger they run in drinking from wells, springs and streams of doubtful purity.

A FEW RULES

A vacation should be a change in occupation, but not too radical a change in habits.

Let the change from winter's mild recreation to summer's active exercise be carefully graduated.

The daily menu on the trip should at least approximate the meals to which one is accustomed at home.

In so far as possible, use the whole summer to recoup the winter's losses in vitality rather than trying to do it all in an intensive two weeks.

A man of 50 cannot safely indulge in all the sports of a boy of 18.

Sufficient sleep is as necessary in summer as in winter.

Light clothing is desirable in hot weather, but a cool evening demands extra wraps.

The tired-out heart cannot suddenly take up the shock of an extra load.

Flabby muscles require graduated exercise to make them strong.

The summer cold is as uncomfortable as the winter gripe and almost as dangerous. Avoid it.

Look over the place where you propose to eat before ordering lunch.

Beware of wayside water supplies and farmhouse wells. Better carry a bottle of water from a protected source.

Habits of decency should not be forgotten in the country any more than at home.

Automobile Deaths Follow Seasonal Movement

THERE is a definite seasonal movement in motor vehicle deaths, according to statistics released by the National Safety Council.

The fall months, beginning in September, are the peak of the year but the toll mounts steadily from April on through the ensuing 8 or 9 months.

As for all accidents, automobile fatalities are more frequent among men than women. In the age group from 20 to 24, the death rate among males is almost five times as high as that among females.

Technical Supervision in the Production of Highest Quality Milk*

JOHN G. HARDENBERGH, V. M. D.

*Director of Laboratories, The Walker-Gordon Laboratory Company, Inc.,
Plainsboro, N. J.*

THE subject of supervision of milk supplies needs no lengthy introduction to emphasize the place which milk holds in the modern scheme of nutrition. Beginning with infancy and extending through the important stages of body growth to maturity, milk and its products have become established in the human dietary to an extent estimated to constitute one-fourth of the total expenditure for food of the average American family. Even this figure is below that recommended as ideal by physiologists, nutrition specialists and economists.

Accepting as a fact that milk is essential to the public health and welfare, it follows that an important place must be given to the supervision of milk production and distribution. In looking back, we find that three principal influences in the evolution of modern milk supplies had their inception some thirty years ago. These were: the work of Pasteur; the introduction of the tuberculin test of dairy cattle; and the pure milk movement initiated somewhat on a philanthropic basis by those who visualized and created what was known as "certified milk."

These three factors have exerted tremendous influence over a period of, roughly, thirty years and, to considerable extent, have reached the peaks of their development in that time. That the persons back of these discoveries and ideals realized the possibilities and future bearing of their efforts seems unlikely, yet concrete evidence of their effect upon the dairy industry is today abundantly available. In this country's more congested centers of population, pasteurization has become the generally accepted method of insuring the safety of fluid milk supplies that cannot be adequately protected by other means. The tuberculin test of dairy cattle has become a requirement in progressive communities whether or not pasteurization is practiced. The pure milk movement, conceived as a specialty,

* Read before Section on Medicine of the American Association for the Advancement of Science, Des Moines, Ia., December, 1929.

into account the element of human nature in following lines of least resistance and the preference in many places for raw milk.

The basic solution for the prevention of bovine tuberculous infection in man naturally rests in the eradication of the bovine disease. This is coming about very rapidly through the operation of the national coöperative program engaged in by the state and federal governments since 1917.

Pasteurization has played a big part in decreasing the incidence of bovine tubercle infection in man, but in a fundamental sense it has served only as a substitute for better means. The health authorities of Chicago recognized this when they made the requirement for tuberculin tested herds, even though the milk from them was to be pasteurized. The idea is becoming increasingly repugnant to all that any process can replace standards of health for dairy herds and dairy employees and standards of sanitation for dairy methods.

To those who are inclined to question the efficiency of the tuberculin test of dairy cattle it may be said that progressive dairymen are not concerned so much about the relatively small number of so-called no-lesion reactors removed from their herds as they are about the possibility of the occasional cow that may be actually infected and yet fail to react. On this point, a few data may be of interest.

In a large dairy herd which has been under federal and state supervision for a number of years, a considerable number of cattle are sold out of the herd each year to slaughter where they are subjected to post-mortem examinations under official inspection, particular attention being given to possible lesions of tuberculosis. Records are available covering the autopsy findings on 2,117 cows (negative to the tuberculin test) sold out of the herd during the past three years. Of these 2,117 cows, only 8, or 0.37 per cent, showed lesions that may have been tuberculous. Of these 8 cases, 2 animals showed calcification of the posterior mediastinal lymph nodes only; 2, hemorrhagic lesions only of the same nodes; 1, a small calcified lesion in the head; 1, calcified lesions on the exterior of the uterus; 1, a calcified lesion in a hepatic lymph node; and 1, skin lesions which proved to harbor acid-fast organisms resembling *Mycobacterium tuberculosis*.

It is interesting to note that not a single case was found in which the presence of a supposedly tuberculous lesion was of such a nature as to be significant either with respect to infection of the milk or to spread of the disease to other animals. The incidence of possible tuberculous lesions (0.37 per cent or 1 in 262) in cows negative to the tuberculin test indicates an efficiency which compares very satisfactorily with any other diagnostic test we know.

Brucella abortus infection.—The part that milk plays in the etiology of *Brucella* infections in man is extremely difficult to appraise at the present time. The state of our knowledge is nothing less than chaotic. Scarcely any two investigators may be found whose ideas are in accord as to the types of organisms isolated from human cases seemingly infected through milk, or who agree as to the exact methods for identification and differentiation of the various strains isolated. It has been very easy to ascribe cases of undulant fever to raw milk and it must be accepted that in some instances the infection has been so acquired. On the other hand, deliberate attempts to produce human infection through the ingestion of milk heavily inoculated with *Brucella abortus* have failed conspicuously.

Epidemiological studies have shown that, in a majority of cases, a history of consuming raw milk may be obtained but, in the same cases, at least 50 per cent had other contacts with *Brucella* infection. In certain sections of the country, Brucellosis in man is obviously milk-borne while in others it is just as obviously an occupational disease. It is a significant fact that those scientists who for many years have studied Bang abortion disease in cattle and related types of infection are the least willing to proffer set opinions and ready solutions for the problem. Therefore, it behooves those of us with lesser experience to be cautious and to await the results of more mature observations before attempting to prove the actual rôle played by milk.

However, so long as there remains a reasonable doubt and so long as milk is reputed to be a danger as a carrier of *Brucella* infections, the supervision of milk supplies must provide for adequate safeguards. This may be accomplished either by pasteurization or by elimination of *Brucella* infections in dairy herds. It must be borne in mind that neither of these systems will affect the complete control of human undulant fever, perhaps not even the major portion of such cases.

With respect to the elimination of Bang abortion disease from dairy herds, it has been demonstrated that the agglutination test is reliable for the detection of *Brucella abortus* infection. The removal of reacting animals will serve to remove those that are shedding the organism in the milk. Exceptions to this are so rare as to have no practical significance. In discussing the efficiency of the agglutination test, a statement has been repeated in medical literature to the effect that many cows eliminate *Brucella abortus* in milk and still fail to react to serum tests. This is a damaging criticism which is not supported by the facts, it being in the nature of a biologic impossibility to have localized infection in the udder without eventual transfer of agglutinins to the blood stream.

HUMAN DISEASES TRANSMISSIBLE THROUGH MILK

In discussing the human diseases it is desired to consider two types of infection: the first, in which the infection of the milk may be direct, as in typhoid fever; the second, in which the infection may be indirect (from man to the udder), as in septic sore throat and scarlet fever.

In the case of typhoid fever, the human carrier is the element which must be eliminated. This is recognized in all well organized supervisory systems that control milk supplies, whether raw or pasteurized. It is essential that all milkers and milk handlers should be examined by suitable tests and every effort made to exclude the possible carrier. Milk has little if any bactericidal action against typhoid bacilli and not even pasteurization can be depended upon as an absolute safety factor if the carrier has access to the milk following the heat treatment. This was illustrated in San Francisco where the work of efficient pasteurization was nullified by a typhoid carrier who operated the bottling and capping machine.

Septic sore throat and scarlet fever are of special interest in milk control work because they present two possibilities in relation to milk infection: the infection may be direct as from a milker or other dairy employee, or it may be indirect as through the infection of a cow's udder by a human carrier. In the case of direct infection, it is not reasonable to suppose that any extensive epidemic could occur, inasmuch as it would be difficult for a human carrier to infect milk so grossly that any considerable portion of it would carry infective dosages. This is particularly true of large supplies wherein the ultimate dilution of any given direct contamination might easily make subsequent human infection an extremely remote possibility.

Furthermore, Jones^{1,2} has shown in his studies of the influence of milk on the growth of scarlet fever streptococci, and in his studies of the bactericidal properties of milk, that certain streptococci of human origin are very susceptible to the effects of milk and that they fail to multiply in fresh unheated milk or in milk heated as high as 62° C. for 20 minutes. The significance of these observations lies in the reasonable supposition that no extensive epidemic of scarlet fever or septic sore throat can occur through the medium of direct human infection of a milk supply.

However, extensive infection of milk supplies with human types of streptococci can occur through the medium of the udder of the cow as a secondary host. This has been the case in several milk-borne epidemics of septic sore throat in which *S. epidemicus* has been inoculated, as it were, into one or more quarters of an udder by an infected

milker; the same occurrence has been noted at least once in the case of *S. scarlatinae*. The subsequent multiplication of these streptococci in the medium furnished by the milk and udder tissues may result in millions of these pathogens being discharged into the milk produced by the infected cow and so into the herd product, since there may be no immediate indication of resulting mastitis to warn the dairyman.

As a rule, in epidemics in which pathogenic streptococci of the human type have been traced to infected milk, we see the combination of a relatively small herd, perhaps only a few cows, the milk from which is sold raw; the presence of a cow with an infected udder; and methods of milk production which pay too little attention to minor udder disturbances and very little attention to the health of dairy employees. Under such conditions, it is possible for a milk supply to carry infective dosages of pathogenic organisms.

In large herds where the milk of any one cow may be mixed with the milk of, say, 100 other cows, the dilution factor may operate to reduce the chances of infective doses of pathogens. We know that such must be the case because cows harboring *S. epidemicus* have been found at a time when there was no occurrence of septic sore throat among the consumers of the milk.

The significance of hemolytic streptococci in milk may be said to depend almost entirely upon whether the species present are of bovine origin, incapable of producing disease in man, or whether they are of human origin, having gained entrance to the milk directly from a human carrier or indirectly through the medium of a cow whose udder has been infected by a human carrier.

So far as beta hemolytic streptococci of bovine origin are concerned, it has been shown that they are commonly found in mixed herd milks, both raw and pasteurized. Several species have been identified, the most frequently occurring being *S. mastitidis*, so named for its association with mastitis in cows. It may also be found living in the udders of cattle with no symptoms of udder inflammation. Its presence is not objectionable except as a possible indication of mastitis and it probably has no true significance as to human health.

Our knowledge of the characteristics of pathogenic types of hemolytic streptococci has been put to the most practical use in the modern laboratory methods for control of certified milk production. Today it is a routine procedure on a few certified milk farms to examine on blood-agar the milk from every fresh and new cow prior to admission to the milking line. In addition, the entire producing herds are checked at frequent intervals by means of group samples which are also plated in blood agar. The occurrence of any suspicious types

of streptococci in such a group sample is followed up by a recheck of the individual cows contributing to the group in order to locate the animal responsible. These laboratory control methods have been described in detail elsewhere.^{3,4}

In this discussion of milk and its relation to the transmission of disease either of human or bovine origin, I have dealt only with some phases of the problem to which special significance is attached by sanitarians. The necessity for intelligent and effective supervision of milk supplies is evident. The supervision must primarily insure adequate protection for the public health and secondarily improve the quality of milk at the source.

Pasteurization has served an indispensable purpose in contributing a relatively high degree of safety to the milk supplies of the more thickly populated sections of the country. Properly applied, the process has a place and a value in the prevention of milk-borne disease that every progressive individual must recognize. With present standards for health and in the present state of development of our milk-production industry, the increasing demand for pasteurization is justified.

We must recognize, however, that neither the heat treatment of milk nor any other processing method removes the causes and defects which make pasteurization necessary. Neither does any heat processing treatment add to the intrinsic value of milk as a food product. These considerations are fundamental problems which leaders in the dairy industry are determined to solve in order that the milk production phase of the dairy industry may keep pace with other developments. The ideal that is being sought is that of a fundamentally sound milk embodying the highest possible attainments in safety, cleanliness and nutritional values at the source. Given such a product it may then be consumed raw or may be subjected to additional processing of proven benefit.

To a considerable extent, the basic principles underlying the production of the highest quality milk have been developed and demonstrated. As stated in the beginning, these requirements are related principally to production management and technical control of production. Production management begins with the fertilization of forage and grain crops to be fed dairy animals, includes the breeding and raising of dairy heifers free of disease, and oversees the feeding and care of the producing cows so that they operate at a maximum of efficiency. The production management must maintain the best conditions under which the cows are stabled and fed; such as cleanliness, ventilation, cleaning and bedding of the cows, condition of the feed and provision for water.

with thermophilic bacteria, which may cause spoilage of the canned product.

Refined sugar has proved to be an outstanding source of thermophilic spoilage bacteria. Sugar is the only ingredient of canned foods in which we have found spores of such bacteria with any degree of frequency. Usually this sugar contamination will not directly cause spoilage but it may result in inoculating the brine tanks or other equipment, where subsequent development may result. In one instance, we have evidence that sugar, highly contaminated with sulphide spoilage bacteria, was directly responsible for substantial loss. All three types of spoilage thermophiles have been found in sugar, but there is no apparent correlation between such contamination and the nature of the raw product (beet or cane) or the degree of refinement. We wish to emphasize the fact, however, that this thermophilic contamination of sugar is not a factor in spoilage in acid products like fruits or tomatoes, since the acidity prevents development of the spores.

No relation has been found between thermophilic spoilage or thermophilic contamination and sanitary conditions in the cannery. It is interesting to note that the same statement has been made with regard to the development of thermophilic contamination in pasteurizing equipment.

Spoilage by putrefactive anaerobes is relatively rare, and, unlike thermophilic spoilage, it may have some relation to sanitary conditions. Where we have studied this type of spoilage, it has resulted through the presence of spores in such things as conveyors and baskets made of porous materials. Soil is considered the source of these bacteria.

The most recent progress in spoilage control is based on prevention. Methods of examination have been developed by which products may be tested during the packing season and the canner told whether there are sources of infection in his equipment.

The methods which are used are selective and vary in reliability. The test for flat-sour bacteria is both practicable and reliable. The colonies are easily recognized and readily counted and are not to be confused with the usual soil-borne thermophilic types. The test for sulphide-spoilage bacteria is striking and is easily applied under field conditions. Colonies can be counted since they appear as intense black spots in the deep medium. The test for gas-forming thermophilic anaerobes is not so satisfactory since these types possess to a marked degree the peculiar property of delayed germination and we have been unable to prepare an ideal medium for their growth. Tests for putrefactive anaerobes are also subject to the limitation imposed

by delayed germination and are therefore largely qualitative. With these last two organisms, counting must be done by the method of dilution.

The problem has been to apply these routine methods of examination over a wide range of territory. A field laboratory has, therefore, been installed in a motor truck which has been in operation for two years. In the summer of 1928 more than 100 mid-west canning factories were covered, and during 1929 a somewhat less number were visited in eastern states.

This truck laboratory is located at central points, samples are collected from surrounding factories, iced and brought to the laboratory. Certain samples are taken from cans just after they have been sealed and before they are processed. These cans give a picture of what has taken place in the cannery in the way of infecting the food. Other samples are taken from various "key" points, such as the brine tanks, conveyors and blanchers, so that if contamination in the canned product is higher than it should be, the source may be traced.

The results of the work have thrown much light on the general subject of sources and methods of contamination and have been of value to individual canning organizations. While, up to the present time, most of the work has been done with canned peas and corn, it is being extended to other products.

While much emphasis has been laid in the past on the need of sanitary inspection of food factories, these studies have shown that something more than a superficial examination of canneries, raw materials and equipment is necessary to insure against spoilage. Canners are realizing more and more that bacteria are their chief enemies, and to keep them in check a bacteriological survey of the type above described is a great help.

Decline of Italian Birth Rate

ACCORDING to reports of the Istituto Centrale di Statistica, the number of births in Italy in 1929 was 1,035,866, or 32,700 less than the preceding year. The birth rate, which in 1928 was 26.08 per 1,000 population, dropped in 1929 to 25.09. The number of deaths in 1928 was 638,818 and in 1929, 660,609, an increase of 21,791. Hence, the mortality rose from 15.59 to 15.98. The excess of births over deaths was 357,257 in 1929, which signified a decrease of 54,491, as compared with 1928.

The Well Baby Clinic at the Office of the Family Physician and Pediatrician*

E. J. HUENEKENS, M. D.

Director, Infant and Preschool Work, Infant Welfare Society, Minneapolis, Minn.

WHEN the Minneapolis Infant Welfare Society was organized in 1910 for the purpose of conducting well baby clinics, the economic status of the parents was not considered, and any infant was welcomed. An intensive educational campaign was conducted so that parents might learn the value of such care. The number of new babies admitted increased each year until 1922 (see Table I), when, due partly to our own investigation (Table II) and partly to the protests of the organized medical profession, our policy of admitting all infants who applied was changed.

Thereafter parents earning \$130 to \$135 a month with only 1 child and no outstanding debts or obligations were not eligible but were referred to their family physician or pediatrician for well baby care. We feel that in the long run this is the fairest policy for an organization dependent on the Community Fund for support. Even though in some cases injustice is done to the individual infant needing well baby care—through unwillingness of parents to pay, or indifference of the physician to whom they are referred—we believe sound policy dictates that the private physician should perform this service, and that such cases should no longer be charged to the community.

In time the physician who is now ignorant of, or indifferent to, preventive well baby care will find himself obliged to give such service, especially as the younger medical graduates have received intensive training in this type of work. To open the eyes of this ignorant or indifferent type of physician is our greatest problem. Some quotations from physicians as reported by mothers to our nurses were:

"No need to bother with any doctor when the baby seems O. K."

"No need of physical examination."

"Clinic doctors are too fussy about babies."

"No use to come so often unless that baby is sick; I haven't time."

"Give him anything that agrees with him. Why experiment?"

* Read at a Joint Session of the American Child Health Association and the Child Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

TABLE I
NEW BABIES ADMITTED TO CLINIC

Year	Resident Births	Infant Mortality Rate	New Babies Admitted	Year	Resident Births	Infant Mortality Rate	New Babies Admitted
1912	6,953	75.2	200	1921	9,436	55.9	3,074
1913	7,124	85.3	371	1922	9,548	53.0	2,659
1914	7,189	83.4	629	1923	9,712	53.8	2,559
1915	8,522	71.1	1,014	1924	9,751	53.4	1,738
1916	8,778	82.4	1,362	1925	9,423	60.8	1,698
1917	8,660	71.6	1,407	1926	9,192	56.3	1,515
1918	8,689	72.0	1,722	1927	8,620	46.5	1,398
1919	8,133	64.6	2,321	1928	8,348	51.0	1,416
1920	9,182	65.2	2,735				

"Use your own judgment; if breast milk does not agree with the baby try some other kind of milk."

These remarks should show why many parents are unwilling to pay for service which does not give them the information and assistance obtained from the free clinics.

The following is a report of a survey made in 1921 by the Minneapolis Infant Welfare Society.

Group—This consisted of 100 cases discharged from Infant Welfare Clinics because the nurse felt that the income of the family was enough to provide for this care by private physician.

Purpose—To find out how many of these 100 cases have consulted private physicians as advised by the nurse.

Type of Wage Earner—This included professional men such as dentists, teachers, ministers; experienced business men such as department managers, salesmen, bank tellers, skilled mechanics, and tradesmen.

Salaries—Salaries range from \$125.00 a month with 1 child, to \$350.00 a month with 4 children. (Salaries alone cannot be taken as an estimate, as the number of children and expenses will vary with every family.)

Result—There were 38 mothers consulting private physicians regularly: 17 a family physician, 21 a pediatrician; 62 are not consulting any doctor.

Special Points—Sixty-seven mothers said that they had a family doctor; 26 had none; and 7 were doubtful. (By family doctor we mean a regular physician to whom the family would turn in case of illness.) Thirteen cases plainly showed the need of special care other than that received from the family doctor; 8 showed the family physician did not care to coöperate with the clinic doctor when the mother was referred to him. Five mothers said they wished to go to a pediatrician but did not like to offend the family doctor; 3 went a few times and said they found it too expensive; 3 felt that they must make payments on home and furniture and could not afford it.

A similar survey is now being made and should show a larger percentage consulting their physician, and also a better type of care being given by the doctors.

While the relationships of the infant welfare society and private

physicians are discussed in terms of our local policy, do not get the idea that it is a purely local problem; on the contrary, infant welfare societies all over the country are battling with the same difficulty, and the solution is yet to be found. However, I believe that the best answer is for the private physician to undertake this work. If some do it poorly at present, we must give them more time. The training of older physicians has been so exclusively in the care of the sick that even such obvious preventive measures as vaccination against smallpox and the inoculation with toxoid or toxin-antitoxin for the prevention of diphtheria seem unimportant and unnecessary.

In private practice, my associate and I give well baby care as follows:

The infant is brought to the office about once every month for the first 9 months; then every 2 months until 13 months old; every 3 months for the balance of the 2d year; and thereafter twice a year, up to school age. The baby is weighed each time and accurate record kept of gains or losses. For the first 6 months the mother is shown how to nurse her baby, and how to express her breasts if the supply runs short; if artificial milk is necessary exact directions are handed her.

In these days of comparatively simple milk mixtures it is not necessary to send a nurse into the home to demonstrate the preparation of

TABLE II

REPORT OF SURVEY OF ONE-TENTH OF ALL REGISTERED CASES
1922-1923

220 Cases

In 29 cases, 13.1 per cent, there was no income; either the baby was illegitimate or the father was unemployed

Income less than \$100

51, 23.1 per cent, were in this class
33, 15 per cent, had 1 child
11, 5 per cent, had 2 children
2, 0.9 per cent, had 3 children
5, 2.2 per cent, had 4 or more

Income between \$100 and \$115

55 cases, 25 per cent, were in this class
29, 13.1 per cent, had 1 child
12, 5.4 per cent, had 2 children
6, 2.7 per cent, had 3 children
8, 3.6 per cent, had 4 or more

Income between \$116 and \$125

46 cases, 20.4 per cent, were in this class
26, 11.8 per cent, had 1 child
11, 5 per cent, had 2 children
6, 2.7 per cent, had 3 children
3, 1.3 per cent, had 4 or more

Income between \$126 and \$135

18 cases, 8.1 per cent, were in this class
8, 3.6 per cent, had 1 child
2, 0.9 per cent, had 2 children
4, 1.8 per cent, had 3 children
4, 1.8 per cent, had 4 or more

Income between \$136 and \$150

14 cases, 6.3 per cent, were in this class
2, 0.9 per cent, had 1 child
4, 1.8 per cent, had 2 children
3, 1.3 per cent, had 3 children
5, 2.2 per cent, had 4 or more

Income between \$151 and \$175

7 cases, 3.1 per cent, were in this class
1, 0.4 per cent, had 1 child
2, 0.9 per cent, had 2 children
3, 1.3 per cent, had 3 children
1, 0.4 per cent, had 4 or more

milk formulas. The mother is directed when to start orange or tomato juice for the prevention of scurvy, and when to begin cod liver oil or viosterol for the prevention of rickets.

During the second 6 months instructions are given as to cereal and vegetable additions to the diet, so that by the time the infant is 10 or 12 months old, it is on three meals a day, and a fairly well mixed diet. During this time the baby is vaccinated and given toxin-antitoxin, the latter followed in 6 months by a Schick test. Through the 2d year the diet is expanded so that by the end the child is receiving all digestible foods in varied preparations.

For the 1st year the charge for this service if given regularly is about two-thirds of the fee for the casual office visit.

During the entire 5-year period mental hygiene instruction is given. The too indulgent or sympathetic mother, the over-stern father, and the nagging parents are dealt with by personal talks and by the required reading of simple popular books on child training, such as Thom's *Everyday Problem of the Everyday Child*, and Blanton's *Child Training*.

Conflicts in methods of discipline between parents are ironed out with varying success and sane sex instruction is urged. The trying problem of anorexia or poor appetite is explained in all its ramifications and early preventive measures along the lines suggested by Aldrich are undertaken. We feel very strongly that proper mental hygiene instruction undertaken very early and carried on through this entire 5-year period will prevent many serious problem cases of later years.

This is a rough outline, and we believe if this program is thoroughly and intelligently carried out preventive well baby care can be given fully as well by the private physician as by the infant welfare clinic.

Development of School Hygiene in France

CONSIDERABLE progress has been made in school hygiene in France in recent years. All the new schools built in the last decade comply with the requirements of hygiene. Through the efforts of a private society, "l'Hygiene par l'Exemple," one well equipped school is built in each department to serve as a model. The improvement is particularly noticeable in Paris and the other large cities where the new schools have large windows, electric lights, hot water heat, and other modern improvements.

Physical examinations of school children are given in Paris and other cities. A bill requiring such examinations throughout the country has been pending in Parliament for some time. School nurses are employed in Paris, and courses for their training have been established. A considerable number of open-air schools has been established.—*Pro Juventute, Zurich, May, 1930, p. 188.*

Waterways Pollution *

THE Conference of State Sanitary Engineers requested its Committee on Sanitary Conservation of Water Resources to submit a report proposing the elements of a model statute for the purpose of conserving water resources.

The committee did so at the meeting of the Conference in Chicago in October, 1928; it was discussed, revised, resubmitted and finally unanimously approved by the Conference.

The Committee on Sanitary Engineering included in a report submitted to the Conference of State and Provincial Health Authorities of North America at its meeting in Washington, D. C., on June 1, 1929, the aforesaid report as approved by the Conference of State Sanitary Engineers, and the Conference of State and Provincial Health Authorities of North America endorsed the principles set forth in said report.

The Committee on Waterways Pollution of the Public Health Engineering Section, American Public Health Association, deems this subject of such importance that the following report is practically identical with that approved by the Conference of State Sanitary Engineers in 1928, and endorsed as to principles by the Conference of State and Provincial Health Authorities of North America in 1929.

The Public Health Engineering Section is composed of engineers engaged in public health work and hence it is postulated that this section looks upon such statutes first for the protection of the public health; second, for the promotion of the public health and the general welfare.

Such statutes to be worth while must be practical, capable of enforcement, intended simultaneously to protect and improve streams, and not place undue burdens upon municipalities and industry. The expenditure of public and private moneys must be kept at a minimum compatible with benefits to the public derived therefrom. The demands of the public for proper expenditure of public funds generally exceed the moneys available from bond issues and taxation. The cost of manufacturing finished goods from raw materials of necessity must include the cost of industrial waste disposal and this is passed on to the consumer. Therefore, in considering statutes and their en-

* Report of the Committee presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting, October 3, 1929.

forcement the very hard facts of the economics of the matter cannot be overlooked.

In consideration of the above the following broad, general, fundamental ideas on legislation are submitted.

PURPOSE OF STATUTES

1. To protect now clean waters against menace to the public health and otherwise so far as is compatible with public interests and urban and industrial development.
2. To improve the sanitary condition of waters now more or less polluted.
3. To render waters increasingly useful to the public as
 - a. Sources of present and future public and municipal water supplies
 - b. Sources of water for industry and agriculture
 - c. Places for recreation in suitable locations

SCOPE OF STATUTORY JURISDICTION

1. Sewage disposal and public sewerage
2. Industrial waste disposal
3. Pollution of waters arising from the development of natural resources

ADMINISTRATION OF STATUTES

As the first and highest use of water is for drinking purposes and as pure drinking water is an essential to the protection of the public health, it is obvious that the administration of such statutes should generally be vested in the state department of health.

In some states local conditions may indicate the wisdom of creating a board or commission to administer such statutes.

As the problem of sewage disposal, sewerage systems, industrial waste disposal, the design and operation of treatment works and the study of the sanitary conditions of waters all involve engineering and its underlying sciences such as hydraulics, chemistry, bacteriology and biology, the department of health or the board or commission must have the services of an adequate bureau of engineering to study projects, conduct investigations, and make reports and recommendation on the manifold and diverse questions which arise. Of much moment is the need for adequate appropriations to finance such work.

GENERAL POLICIES

The statutes should provide for the submission of plans, relevant data and reports to the state authorities as to existing and proposed

1. Sewerage systems
2. Means of sewage disposal (including treatment works)

3. Sources, nature and amount of industrial wastes together with means of disposal (including treatment works or admission to sewer system)
4. Means of disposal for pollution arising from development of natural resources

Upon receipt of such data an engineering study and, if necessary, a field inspection should be made thereof to determine:

1. Compliance with sound engineering practice
2. Practicability and feasibility of the project
3. Sufficiency of the existing or proposed means of disposal or degree of treatment adequately to protect public interests in the use of the receiving body of water

If the project be found satisfactory the statute should empower the state authorities to issue to the applicant a formal permit:

1. Approving the plans or project "as is" or with such modifications as are deemed necessary
2. Stipulating the conditions under which the discharge is permitted or the works are to be operated

The statute should vest in the state authorities full jurisdiction over:

1. New or increased discharge of sewage
2. New discharge of industrial waste or increase in the pollution strength of existing discharge of industrial wastes
3. New pollution arising from the development of natural resources

It should vest in the state authorities discretionary police power in cases where existing discharge of sewage or industrial waste is demonstrated to constitute a menace to the public health or prejudicial to public interests.

IN RE SEWERAGE

Municipalities of sufficient size and population to warrant it should prepare, adopt and submit for approval to the state authorities a comprehensive sewerage plan to show at least:

1. All existing sewers
2. Proposed sewer extensions in those parts of the town site for which there is a city plan
3. Estimate of future rate of flow from now undeveloped parts of the town site in order that the main sewers and works of the comprehensive plan shall have adequate capacity
4. Studies as to the practicability and advisability of admitting sewage from outside the town but originating on the same drainage area
5. The admissibility "as is" or with preliminary treatment of industrial wastes to the public sewer system
6. Intercepting and outfall sewers to convey sewage to a suitable site for disposal or treatment
7. Where sewage is to be treated, plans of the necessary first units and general

outline plans sufficient to show the feasibility of extending the capacity of the works or providing for more refined treatment if and when needed

The statutes should enable municipalities to do the following:

1. Exercise the right of eminent domain to acquire land or rights needed for the construction of sewers, treatment works and appurtenances.
2. Issue bonds and create sinking funds to finance construction.
3. Assess the cost of main and branch sewers against abutting property owners.
4. Charge sewer rental to finance the operation, maintenance, enlargement or betterment of treatment works and appurtenances.
5. Establish a special sewerage fund by taxation or annual appropriation for the sole purpose of building and maintaining main sewerage systems and treatment works.
6. Enter into agreements with contiguous or neighboring municipalities for conveyance and disposal of sewage or for the joint construction, maintenance and operation of sewers, treatment works and appurtenances and for the equitable distribution of the costs thereof and for joint management of the commonly used works.

IN RE INDUSTRIAL WASTES

The statutes should empower the state authorities to take care of the following:

1. Order the installation of industrial waste treatment works in cases where "reasonable and practicable ways and means" are known and where the lack of such installation results in pollution of the receiving body of water which constitutes a menace to the public health or is prejudicial to public interests.
2. By themselves or in coöperation with industry, conduct investigations concerning industrial wastes, their treatment and disposal in cases where there are not now known "reasonable and practicable ways and means" for treatment and disposal.
3. Make scientific studies to determine the sanitary condition of water resources and their present and probable future uses to serve best the public interests.
4. Allocate water resources for various public uses so as to bring about the best and highest utilization of the several streams, lakes and parts thereof.

IN RE DEVELOPMENT OF NATURAL RESOURCES

There should be statutory authority vesting in the state authorities discretionary powers to regulate and control, so far as is reasonable and practicable, the pollution of water resources arising from the development of natural resources so as to foster simultaneously the utilization of mineral wealth and protect the streams draining such regions.

Factories can be located in suitable places, but mineral resources must be developed *in situ*.

ADMINISTRATION AND ENFORCEMENT

Such statutes, powers and duties should be administered with even-handed justice to the end that the commonwealth, its municipalities, its citizens, and its industries are benefitted, not harmed.

To that end the state authorities should offer helpful counsel, lead the way, guide and direct rather than arbitrarily issue formal orders without considering the practicability of their being carried out.

However, when in the administration of the statutes it does become necessary to invoke the police power of the state and issue a formal order, it should be so worded and in such terms that, if not obeyed and the case comes before a court for adjudication, there will be no difficulty in the Attorney General proving to the court the justice and equity of the order so that it will be sustained even upon appeal.

No action should be started that cannot be successfully finished.

Fines and imprisonment for violation of such statutes may intimidate the smaller towns and corporations but in the last analysis they are merely punitive and the end result of the enactment and enforcement should be money spent on construction, rather than paid into a public treasury and the nuisance continued.

For wilful stream pollution from non-going concerns, as for example the heedless emptying of vats in an abandoned factory, or the discharge of unsaleable milk from a receiving station, a money fine is the only redress and acts as a deterrent to such a flagrant practice.

Special Inspectors of Child Labor in Czechoslovakia

ON February 26, 1930, the Minister of Social Welfare of Czechoslovakia issued a circular to the factory inspection authorities in which he announced that a special division had been established in his ministry for better enforcement of the child labor law. The work is to be carried out by inspectors selected from the regular factory inspection staff. These government inspectors are to coöperate with the trade unions of young workers. The circular states specifically that the work of the new division will not be limited to the enforcement of labor legislation but will also occupy itself with other welfare problems of young workers.—*Lehrlings-schutz, Jugend- und Berufsfürsorge*, Apr., 1930, p. 22.

PSITTACOSIS

PSITTACOSIS does not rank very high in order of numerical importance among the diseases acquired by man from the lower animals, but it stands second to none in interest from the scientific point of view.

The disease was recognized in 1879 by Ritter, who was not only a keen clinician but a shrewd observer, as he recognized the etiological significance of birds; since that time isolated cases, and more or less extensive outbreaks have occurred in most countries of western Europe as well as on this side of the Atlantic.

Our present interest springs from the epidemic which had its inception in the United States at just about the turn of the year. Many cases were traceable to parrots presented as tokens of Yuletide greetings, but they were, in fact, carriers of the disease to many, and of death to a few.

Approximately 150 cases have occurred, with 25 fatalities. It is a very safe assumption that the true figures of incidence and fatality would be higher than those given, since unless one has the clue (and recognizes it) in the shape of a bird, usually a sick one, the case will certainly pass as atypical influenza or atypical pneumonia. The newspapers have rendered excellent service in calling attention to the outbreak; indeed, without their aid, many cases, perhaps the majority of those reported, would have appeared in morbidity and mortality records under other diagnoses.

During the past few months the disease has attracted attention

in South America, England and Germany, as well as this country; in each it has taken its toll among those exposed.

Once the disease is suspected the clinical diagnosis is relatively simple. The onset with chill, headache, and fever without catarrhal symptoms is suggestive; when such manifestations are followed by physical signs in the chest indicative of pneumonia, but unaccompanied by the usual symptoms of that disease, with the symptoms insignificant or out of proportion to the physical signs, the diagnosis may be considered as established. Laboratory methods are of little value in diagnosis, save perhaps that a low leucocyte count speaks against pneumonia of the ordinary sort.

As to the bird carriers, parrots stand first, parrakeets (love birds) next, and it is believed that canaries are not beyond suspicion. The presence of a bird—sick or well—should serve to put the physician and the health officer on guard. The bird usually is decidedly ill and often dies, but cases have occurred from association with birds showing little or no evidence of illness. Usually a newly acquired bird is the source of infection, though this is not always true.

The research work carried out during the present epidemic seems to exclude Nocard's bacillus (a member of the paratyphoid group) as the cause of the disease and points to a filtrable virus as the essential etiological agent.

Of great importance and interest have been the laboratory outbreaks. Infections of research workers have accounted for the death of Dr. William R. Stokes, of the Baltimore City Health Department, and of Harry B. Anderson, of the Hygienic Laboratory of the U. S. Public Health Service. The most extensive outbreak was that occurring at the Hygienic Laboratory. Eleven cases occurred, only 2 of which were due to direct exposure to infected birds. The exact mode of infection in the remaining 9 cases is unknown.

It is evident that we have in psittacosis a disease demanding much research, but the fact that the research is especially hazardous will not deter those carrying on the necessary investigations.

From the point of view of public health procedure the problem seems very simple. The individual may protect himself by refraining from keeping parrots and certain other birds, or from exposing himself to them. In the present state of our knowledge, an embargo on suspected birds seems to be the only solution, from the point of view of public health authorities, national and local, and indeed, it is a question whether all birds of the susceptible group should not be considered as coming under suspicion.

WHAT IS THE SATURATION POINT FOR CITY NOISE?

THAT noise is unavoidable where people gather themselves together in communities is a fact as ancient as the man-made institution of cities and towns, but never before in the history of the world has there been such a constant clamor as is produced in modern cities or one made up of so many startling, alarm-like elements.

To a certain extent we can and do adapt ourselves to the conditions of noise, but common experience shows that there are limits to this adaptation. Everyone who has tried to sleep through the hum of after-theater traffic interspersed with nervous tooting of horns, through the rattle of milk delivery, through the clatter of ash collection—all the noises of a city night—knows that custom does not mitigate the annoyance caused by noise. Everyone who has tried to do a piece of work in the din of adding machines, typewriters, telephone bells and office conversation knows that he is disturbed by these things—at some times more than at other times, to be sure, but nevertheless appreciably disturbed. Business firms, realizing this disturbing effect of noise on workers, willingly spent over \$3,000,000 last year in the attempt to dampen office noises and exclude street noises.

The researches of psychologists so far have been a confirmation of this common experience, usually revealing that noise has been more of a handicap to rest and to work than the average man ever suspected.

One question has not been answered in laboratories and it is doubtful if it can be answered there, where conditions are sifted of many of the elements of everyday life: What is the saturation point for city noise—the point beyond which human adaptation cannot compensate for the tax noise levies on the attention, on the energy, and on the relaxation periods?

A pragmatic answer is given in the letters sent to the Health Department over a period of years complaining of noise in the five boroughs of Greater New York. The very fact that people have written these letters after a period of suffering is an answer to the question: How much noise can individuals stand?

We say, "after a period of suffering," advisedly. A study of these letters reveals that, while one out of twenty-five may be from a crank, the other twenty-four are from sensible people who have delayed making their complaints until they could endure conditions no longer. One letter, for example, tells of night riveting that had gone on for three months before the people in a neighboring apartment house decided to complain; another from the dean of women of a leading college protested against the clangor of street traffic that had disturbed a whole semester's work in the classrooms on the exposed side of the

buildings; and school principals had figures to prove the slowing up of the whole year's work by the constant disturbance of recitations by noise from outside. So it goes through the voluminous files that house these complaints—the majority of the complaints show that stable, serious people are disturbed by noise to the point where they feel that they cannot adapt themselves to it.

It seems significant that these people should turn for help to their department of health. With an instinctive logic, they recognize noise as a health problem—a serious hindrance to their well-being and efficiency. Whether or not noise has reached its worst proportions at this time, it surely has reached a point where something must be done to give people relief from it—something more than the abating of individual noises when and as complaints are made of them.

Another thing—significant of the way the noise nuisance has projected itself into the minds of thinking people as a problem that must be solved now—is the alacrity with which the members of the New York Noise Abatement Commission entered into their work. Not one of the fourteen men invited last October to serve on this commission—and they knew they would have much hard work to do—refused to perform his patriotic task. Doctors, lawyers, builders, engineers, executives of large organizations, all had found noise a great handicap in their varied work and had already given much thought to its curbing.

The noise survey of the city, conducted by the Noise Abatement Commission during its first four months, reveals tremendous peaks of noise at certain places and at certain hours—noise that piles up as high as 94 decibels down on Cortland Street where the radio shops are congregated, and 76 decibels at many of the street corners where cross town trucking is heaviest. This approaches the 100 decibel limit, which is the point where sound is so loud that it sets the ear tingling. This would seem to be a point where continued noise creates physical discomfort.

The survey further reveals that the din of traffic cluttered streets travels up as high as the thirtieth floor of office buildings and that a full medley of city noise reaches up even higher—to the very topmost floors of isolated skyscrapers.

Perhaps we cannot truly say that the noise of the city has reached the saturation point in view of the fact that there are still oases of comparative quiet—like the Mall in Central Park, the first set-back stories of the new style skyscrapers that are protected from street noise by the sound-shadow of the out-jutting stories below, and a few residence streets in Brooklyn where the sound of baby carriage wheels is recorded by the noise testing machines used in the survey.

The fact remains that unnecessary noises surround most of the six million New Yorkers during all their working hours and most of their sleeping hours. Many people never have a chance to recover from the effects of one group of noises before they are exposed to another group. Already noises, or rather the causes of noise, are so closely interwoven with our economic and industrial life that it will take the combined ingenuity of builders, acoustical engineers, automobile builders, and lawyers to change present conditions without working hardship on any group in the community. Fortunately the Noise Abatement Commission is made up of men equipped by their life training to deal with the many ramifications of this modern public health problem and make New York a more comfortable, more livable city for all classes of people living in it.

CONGRESS AUTHORIZES NATIONAL INSTITUTE OF HEALTH

THE bill for a National Institute of Health, which has been pending before Congress for several years, was passed late in May, and signed by the President. This measure, which had been endorsed by the American Public Health Association, changes the name of the Hygienic Laboratory of the U. S. Public Health Service to National Institute of Health, authorizes the appropriation of \$750,000 for its expansion, permits the government to accept unconditional gifts and donations for investigations of human diseases and public health conditions, and allows qualified scientists to be appointed fellows at the newly created Institute. The bill was sponsored by Senator Joseph E. Ransdell of Louisiana. It is gratifying to know that Congress is sufficiently interested in public health, in the midst of its discussions of the tariff and other important matters, to pass this measure.

ASSOCIATION NEWS

Cathedral, Mexico City

A NINE-DAY, ALL-EXPENSE TOUR WITH 5 DAYS IN MEXICO CITY,

FROM THURSDAY, MIDNIGHT, OCTOBER 30, TO SATURDAY, NOVEMBER 8, 1930

FOR MEMBERS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION AND
THEIR FAMILIES, FOLLOWING THE FIFTY-NINTH ANNUAL MEETING
OF THE ASSOCIATION IN FORT WORTH, TEX., OCTOBER 27 TO 30, 1930

THE Chief of the Department of Health of the Republic of Mexico, Dr. Rafael Silva, has, in the name of the department and with the approval of the President of the Republic, invited the members of the American Public Health Association to visit Mexico City following the Annual Meeting in Fort Worth, for the purpose of meeting the public health workers of Mexico and participating in a scientific program of interest to American public health work-

ers. At the same time members of the Association are invited to be the official guests of the government at a number of entertainments.

In addition, the members of the Association in San Antonio, Tex., have invited the delegates to stop over for a visit in San Antonio and to participate in a brief meeting in that city.

In order to make the acceptance of this invitation convenient for the members of the Association and to reduce the

expense, an all-expense tour on a special train has been arranged.

The preliminary itinerary and program follow:

Thursday, October 30—

10.00 P.M.—Cars open—Fort Worth

Friday, October 31—

12.30 A.M.—Lv. Fort Worth

Breakfast on train

9.00 A.M.—Ar. San Antonio

9.15 A.M.—Tour of the city, visiting
The Alamo, Medina Lake,
etc.

12.15 P.M.—Return to Hotel

12.30 P.M.—Luncheon

Afternoon—At leisure

4.00 P.M.—Lv. San Antonio

Dinner on train

8.30 P.M.—Ar. Eagle Pass

Saturday, November 1—

Breakfast on train

8.00 A.M.—Ar. Monterrey—tour of city
including El Canon,
Bishop Palace, etc.

10.30 A.M.—Lv. Monterrey

Luncheon on train

Dinner on train

Sunday, November 2—

Breakfast on train

9.00 A.M.—Ar. Mexico City

9.30 A.M.—Excursion to San Juan Teotihuacan (Pyramids, Museum and Garden)

12.00 M. —Luncheon, Gruta Restaurant,
under auspices of Secretary of Public Education

2.00 P.M.—Return to Mexico City

4.00 P.M.—Folklore Pageant at Centro
Venustrano Carranza
(Outdoor Theatre) under

the auspices of Federal
District of Mexico

Evening—At leisure

Monday, November 3—

9.30 A.M.—Meeting of the Delegation
with the Department of
Public Health of the Re-
public of Mexico—Assem-
bly High School Auditor-
ium or at the Department
of Public Health

PROGRAM

1. Address of Welcome—DR. RAFAEL SILVA, Chief of the Department of Public Health of Mexico
 2. Reply to Address of Welcome—A. J. CHESLEY, M.D., President of A. P. H. A., HUGH S. CUMMING, M.D., Surgeon General of the U. S. Public Health Service, Washington, D. C., and J. C. ANDERSON, M.D., State Health Officer of Texas
 3. History of Health in Mexico—DR. ULISES VALDES, Secretary General of the Department of Public Health.
 4. Local Public Health Work—DR. MIGUEL BUSTAMANTE, Director of Health Unit at Vera Cruz, Ver.
 5. Display of film showing public health work in Mexico
- 1.00 P.M.—Luncheon
- 4.00 P.M.—Reception and meeting of President Ortiz Rubio, Chapultepec Castle
- 9.00 P.M.—Banquet and Dance, Auspices of Department of the Central Federal District of Mexico

Tuesday, November 4—

9.30 A.M.—Scientific session

PROGRAM

1. Address—W. S. RANKIN, M.D., Chairman, Executive Board, A. P. H. A., Duke Endowment, Charlotte, N. C.
 2. Address—B. J. LLOYD, M.D., Pan American Sanitary Bureau, Washington, D. C.
 3. Safeguarding a City Milk Supply—H. V. CARDONA, D.V.M., Supervisor of Milk Sanitation, Department of Public Health and Welfare, Fort Worth, Tex.
- 12.00 M. —Drive to the Desierto de los leones (Desert of Lions)
Luncheon, under the auspices of the Secretary of Public Works

Xochimilco's Floating Gardens

2.00 P.M.—Return to Mexico City, with a tour of the city, including the Cathedral, The Plaza de Toros, Chapultepec Castle (the White House of Mexico and former home of Maximilian and Carlotta), etc.

Evening—At leisure

Wednesday, November 5—

9.30 A.M.—Tour of inspection of the beautiful new buildings of the National Department of Health

12.00 M. —Depart for Xochimilco—Luncheon under auspices of Department of Public Health

3.00 P.M.—Walk in Gardens and gondola tour of canals of Xochimilco

Inspection of Mexico City Water Supply

Evening—Concert

Thursday, November 6—

The delegates will be at leisure to make their own arrangements individually or in groups for additional sight-seeing or visits to places not included in the previous four days.

8.30 P.M.—Lv. Mexico City

Friday, November 7—

7.00 A.M.—Breakfast on train

12.00 M. —Luncheon on train

6.30 P.M.—Dinner on train

Saturday, November 8—

2.00 A.M.—Ar. Eagle Pass

7.00 A.M.—Ar. San Antonio

7.15 A.M.—Breakfast on train

12.00 M. —Luncheon on train

3.30 P.M.—Ar. Fort Worth

The total cost of the tour, including all expenses from Fort Worth to Mexico City and return to Fort Worth, with stop-over in San Antonio, including sight-seeing, transportation, all meals en route and during five days in Mexico City, all side trips, and the use of pullman cars in Mexico City, is to be as follows:

1 person in upper berth—\$112.40
1 person in lower berth—\$149.90
2 persons in lower berth—\$126.15 each
2 persons in a section—\$131.15 each
3 persons in a section—\$121.55 each
2 persons in a compartment—\$169.90 each
3 persons in a compartment—\$147.40 each
2 persons in a drawing-room—\$189.90 each
3 persons in a drawing-room—\$160.75 each

Assurance has been given that the most modern equipment will be used on the special train, including observation car, maid and valet service, shower bath, dining car, baggage car and probably a radio. An individual making the trip by himself would need to spend approximately \$250 to cover the same ground.

Application for a place in the delegation should be made on the following blank, and this sent to the Executive Secretary of the Association.

Homer N. Calver, Executive Secretary,
American Public Health Association,
370 Seventh Ave., New York, N. Y.

Please reserve in the Delegation of the A. P. H. A. to Mexico City

Space desired

I will be accompanied by

I am a member of the American Public Health Association

Please send me a membership application blank

by delayed germination and are therefore largely qualitative. With these last two organisms, counting must be done by the method of dilution.

The problem has been to apply these routine methods of examination over a wide range of territory. A field laboratory has, therefore, been installed in a motor truck which has been in operation for two years. In the summer of 1928 more than 100 mid-west canning factories were covered, and during 1929 a somewhat less number were visited in eastern states.

This truck laboratory is located at central points, samples are collected from surrounding factories, iced and brought to the laboratory. Certain samples are taken from cans just after they have been sealed and before they are processed. These cans give a picture of what has taken place in the cannery in the way of infecting the food. Other samples are taken from various "key" points, such as the brine tanks, conveyors and blanchers, so that if contamination in the canned product is higher than it should be, the source may be traced.

The results of the work have thrown much light on the general subject of sources and methods of contamination and have been of value to individual canning organizations. While, up to the present time, most of the work has been done with canned peas and corn, it is being extended to other products.

While much emphasis has been laid in the past on the need of sanitary inspection of food factories, these studies have shown that something more than a superficial examination of canneries, raw materials and equipment is necessary to insure against spoilage. Canners are realizing more and more that bacteria are their chief enemies, and to keep them in check a bacteriological survey of the type above described is a great help.

Decline of Italian Birth Rate

ACCORDING to reports of the Istituto Centrale di Statistica, the number of births in Italy in 1929 was 1,035,866, or 32,700 less than the preceding year. The birth rate, which in 1928 was 26.08 per 1,000 population, dropped in 1929 to 25.09. The number of deaths in 1928 was 638,818 and in 1929, 660,609, an increase of 21,791. Hence, the mortality rose from 15.59 to 15.98. The excess of births over deaths was 357,257 in 1929, which signified a decrease of 54,491, as compared with 1928.

The Well Baby Clinic at the Office of the Family Physician and Pediatrician *

E. J. HUENEKENS, M. D.

Director, Infant and Preschool Work, Infant Welfare Society, Minneapolis, Minn.

WHEN the Minneapolis Infant Welfare Society was organized in 1910 for the purpose of conducting well baby clinics, the economic status of the parents was not considered, and any infant was welcomed. An intensive educational campaign was conducted so that parents might learn the value of such care. The number of new babies admitted increased each year until 1922 (see Table I), when, due partly to our own investigation (Table II) and partly to the protests of the organized medical profession, our policy of admitting all infants who applied was changed.

Thereafter parents earning \$130 to \$135 a month with only 1 child and no outstanding debts or obligations were not eligible but were referred to their family physician or pediatrician for well baby care. We feel that in the long run this is the fairest policy for an organization dependent on the Community Fund for support. Even though in some cases injustice is done to the individual infant needing well baby care—through unwillingness of parents to pay, or indifference of the physician to whom they are referred—we believe sound policy dictates that the private physician should perform this service, and that such cases should no longer be charged to the community.

In time the physician who is now ignorant of, or indifferent to, preventive well baby care will find himself obliged to give such service, especially as the younger medical graduates have received intensive training in this type of work. To open the eyes of this ignorant or indifferent type of physician is our greatest problem. Some quotations from physicians as reported by mothers to our nurses were:

"No need to bother with any doctor when the baby seems O. K."

"No need of physical examination."

"Clinic doctors are too fussy about babies."

"No use to come so often unless that baby is sick; I haven't time."

"Give him anything that agrees with him. Why experiment?"

* Read at a Joint Session of the American Child Health Association and the Child Hygiene Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 2, 1929.

TABLE I

NEW BABIES ADMITTED TO CLINIC

Year	Resident Births	Infant Mortality Rate	New Babies Admitted	Year	Resident Births	Infant Mortality Rate	New Babies Admitted
1912	6,953	75.2	200	1921	9,436	55.9	3,074
1913	7,124	85.3	371	1922	9,548	53.0	2,659
1914	7,189	83.4	629	1923	9,712	53.8	2,559
1915	8,522	71.1	1,014	1924	9,751	53.4	1,738

1920	9,182	65.2	2,735				

"Use your own judgment; if breast milk does not agree with the baby try some other kind of milk."

These remarks should show why many parents are unwilling to pay for service which does not give them the information and assistance obtained from the free clinics.

The following is a report of a survey made in 1921 by the Minneapolis Infant Welfare Society.

Group—This consisted of 100 cases discharged from Infant Welfare Clinics because the nurse felt that the income of the family was enough to provide for this care by private physician.

Purpose—To find out how many of these 100 cases have consulted private physicians as advised by the nurse.

Type of Wage Earner—This included professional men such as dentists, teachers, ministers; experienced business men such as department managers, salesmen, bank tellers, skilled mechanics, and tradesmen.

Salaries—Salaries range from \$125.00 a month with 1 child, to \$350.00 a month with 4 children. (Salaries alone cannot be taken as an estimate, as the number of children and expenses will vary with every family.)

Result—There were 38 mothers consulting private physicians regularly: 17 a family physician, 21 a pediatrician; 62 are not consulting any doctor.

Special Points—Sixty-seven mothers said that they had a family doctor; 26 had none; and 7 were doubtful. (By family doctor we mean a regular physician to whom the family would turn in case of illness.) Thirteen cases plainly showed the need of special care other than that received from the family doctor; 8 showed the family physician did not care to coöperate with the clinic doctor when the mother was referred to him. Five mothers said they wished to go to a pediatrician but did not like to offend the family doctor; 3 went a few times and said they found it too expensive; 3 felt that they must make payments on home and furniture and could not afford it.

A similar survey is now being made and should show a larger percentage consulting their physician, and also a better type of care being given by the doctors.

While the relationships of the infant welfare society and private

physicians are discussed in terms of our local policy, do not get the idea that it is a purely local problem; on the contrary, infant welfare societies all over the country are battling with the same difficulty, and the solution is yet to be found. However, I believe that the best answer is for the private physician to undertake this work. If some do it poorly at present, we must give them more time. The training of older physicians has been so exclusively in the care of the sick that even such obvious preventive measures as vaccination against small-pox and the inoculation with toxoid or toxin-antitoxin for the prevention of diphtheria seem unimportant and unnecessary.

In private practice, my associate and I give well baby care as follows:

The infant is brought to the office about once every month for the first 9 months; then every 2 months until 13 months old; every 3 months for the balance of the 2d year; and thereafter twice a year, up to school age. The baby is weighed each time and accurate record kept of gains or losses. For the first 6 months the mother is shown how to nurse her baby, and how to express her breasts if the supply runs short; if artificial milk is necessary exact directions are handed her.

In these days of comparatively simple milk mixtures it is not necessary to send a nurse into the home to demonstrate the preparation of

TABLE II

REPORT OF SURVEY OF ONE-TENTH OF ALL REGISTERED CASES
1922-1923

220 Cases

In 29 cases, 13.1 per cent, there was no income; either the baby was illegitimate or the father was unemployed

3, 1.3 per cent, had 4 or more	1, 0.4 per cent, had 4 or more

milk formulas. The mother is directed when to start orange or tomato juice for the prevention of scurvy, and when to begin cod liver oil or viosterol for the prevention of rickets.

During the second 6 months instructions are given as to cereal and vegetable additions to the diet, so that by the time the infant is 10 or 12 months old, it is on three meals a day, and a fairly well mixed diet. During this time the baby is vaccinated and given toxin-antitoxin, the latter followed in 6 months by a Schick test. Through the 2d year the diet is expanded so that by the end the child is receiving all digestible foods in varied preparations.

For the 1st year the charge for this service if given regularly is about two-thirds of the fee for the casual office visit.

During the entire 5-year period mental hygiene instruction is given. The too indulgent or sympathetic mother, the over-stern father, and the nagging parents are dealt with by personal talks and by the required reading of simple popular books on child training, such as Thom's *Everyday Problem of the Everyday Child*, and Blanton's *Child Training*.

Conflicts in methods of discipline between parents are ironed out with varying success and sane sex instruction is urged. The trying problem of anorexia or poor appetite is explained in all its ramifications and early preventive measures along the lines suggested by Aldrich are undertaken. We feel very strongly that proper mental hygiene instruction undertaken very early and carried on through this entire 5-year period will prevent many serious problem cases of later years.

This is a rough outline, and we believe if this program is thoroughly and intelligently carried out preventive well baby care can be given fully as well by the private physician as by the infant welfare clinic.

Development of School Hygiene in France

CONSIDERABLE progress has been made in school hygiene in France in recent years. All the new schools built in the last decade comply with the requirements of hygiene. Through the efforts of a private society, "l'Hygiene par l'Exemple," one well equipped school is built in each department to serve as a model. The improvement is particularly noticeable in Paris and the other large cities where the new schools have large windows, electric lights, hot water heat, and other modern improvements.

Physical examinations of school children are given in Paris and other cities. A bill requiring such examinations throughout the country has been pending in Parliament for some time. School nurses are employed in Paris, and courses for their training have been established. A considerable number of open-air schools has been established.—*Pro Juventute, Zurich, May, 1930, p. 188.*

Waterways Pollution*

THE Conference of State Sanitary Engineers requested its Committee on Sanitary Conservation of Water Resources to submit a report proposing the elements of a model statute for the purpose of conserving water resources.

The committee did so at the meeting of the Conference in Chicago in October, 1928; it was discussed, revised, resubmitted and finally unanimously approved by the Conference.

The Committee on Sanitary Engineering included in a report submitted to the Conference of State and Provincial Health Authorities of North America at its meeting in Washington, D. C., on June 1, 1929, the aforesaid report as approved by the Conference of State Sanitary Engineers, and the Conference of State and Provincial Health Authorities of North America endorsed the principles set forth in said report.

The Committee on Waterways Pollution of the Public Health Engineering Section, American Public Health Association, deems this subject of such importance that the following report is practically identical with that approved by the Conference of State Sanitary Engineers in 1928, and endorsed as to principles by the Conference of State and Provincial Health Authorities of North America in 1929.

The Public Health Engineering Section is composed of engineers engaged in public health work and hence it is postulated that this section looks upon such statutes first for the protection of the public health; second, for the promotion of the public health and the general welfare.

Such statutes to be worth while must be practical, capable of enforcement, intended simultaneously to protect and improve streams, and not place undue burdens upon municipalities and industry. The expenditure of public and private moneys must be kept at a minimum compatible with benefits to the public derived therefrom. The demands of the public for proper expenditure of public funds generally exceed the moneys available from bond issues and taxation. The cost of manufacturing finished goods from raw materials of necessity must include the cost of industrial waste disposal and this is passed on to the consumer. Therefore, in considering statutes and their en-

* Report of the Committee presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-eighth Annual Meeting, October 3, 1929.

forcement the very hard facts of the economics of the matter cannot be overlooked.

In consideration of the above the following broad, general, fundamental ideas on legislation are submitted.

PURPOSE OF STATUTES

1. To protect now clean waters against menace to the public health and otherwise so far as is compatible with public interests and urban and industrial development.
2. To improve the sanitary condition of waters now more or less polluted.
3. To render waters increasingly useful to the public as
 - a. Sources of present and future public and municipal water supplies
 - b. Sources of water for industry and agriculture
 - c. Places for recreation in suitable locations

SCOPE OF STATUTORY JURISDICTION

1. Sewage disposal and public sewerage
2. Industrial waste disposal
3. Pollution of waters arising from the development of natural resources

ADMINISTRATION OF STATUTES

As the first and highest use of water is for drinking purposes and as pure drinking water is an essential to the protection of the public health, it is obvious that the administration of such statutes should generally be vested in the state department of health.

In some states local conditions may indicate the wisdom of creating a board or commission to administer such statutes.

As the problem of sewage disposal, sewerage systems, industrial waste disposal, the design and operation of treatment works and the study of the sanitary conditions of waters all involve engineering and its underlying sciences such as hydraulics, chemistry, bacteriology and biology, the department of health or the board or commission must have the services of an adequate bureau of engineering to study projects, conduct investigations, and make reports and recommendation on the manifold and diverse questions which arise. Of much moment is the need for adequate appropriations to finance such work.

GENERAL POLICIES

The statutes should provide for the submission of plans, relevant data and reports to the state authorities as to existing and proposed

1. Sewerage systems
2. Means of sewage disposal (including treatment works)

3. Sources, nature and amount of industrial wastes together with means of disposal (including treatment works or admission to sewer system)
4. Means of disposal for pollution arising from development of natural resources

Upon receipt of such data an engineering study and, if necessary, a field inspection should be made thereof to determine:

1. Compliance with sound engineering practice
2. Practicability and feasibility of the project
3. Sufficiency of the existing or proposed means of disposal or degree of treatment adequately to protect public interests in the use of the receiving body of water

If the project be found satisfactory the statute should empower the state authorities to issue to the applicant a formal permit:

1. Approving the plans or project "as is" or with such modifications as are deemed necessary
2. Stipulating the conditions under which the discharge is permitted or the works are to be operated

The statute should vest in the state authorities full jurisdiction over:

1. New or increased discharge of sewage
2. New discharge of industrial waste or increase in the pollution strength of existing discharge of industrial wastes
3. New pollution arising from the development of natural resources

It should vest in the state authorities discretionary police power in cases where existing discharge of sewage or industrial waste is demonstrated to constitute a menace to the public health or prejudicial to public interests.

IN RE SEWERAGE

Municipalities of sufficient size and population to warrant it should prepare, adopt and submit for approval to the state authorities a comprehensive sewerage plan to show at least:

1. All existing sewers
2. Proposed sewer extensions in those parts of the town site for which there is a city plan
3. Estimate of future rate of flow from now undeveloped parts of the town site in order that the main sewers and works of the comprehensive plan shall have adequate capacity
4. Studies as to the practicability and advisability of admitting sewage from outside the town but originating on the same drainage area
5. The admissibility "as is" or with preliminary treatment of industrial wastes to the public sewer system
6. Intercepting and outfall sewers to convey sewage to a suitable site for disposal or treatment
7. Where sewage is to be treated, plans of the necessary first units and general

outline plans sufficient to show the feasibility of extending the capacity of the works or providing for more refined treatment if and when needed

The statutes should enable municipalities to do the following:

1. Exercise the right of eminent domain to acquire land or rights needed for the construction of sewers, treatment works and appurtenances.
2. Issue bonds and create sinking funds to finance construction.
3. Assess the cost of main and branch sewers against abutting property owners.
4. Charge sewer rental to finance the operation, maintenance, enlargement or betterment of treatment works and appurtenances.
5. Establish a special sewerage fund by taxation or annual appropriation for the sole purpose of building and maintaining main sewerage systems and treatment works.
6. Enter into agreements with contiguous or neighboring municipalities for conveyance and disposal of sewage or for the joint construction, maintenance and operation of sewers, treatment works and appurtenances and for the equitable distribution of the costs thereof and for joint management of the commonly used works.

IN RE INDUSTRIAL WASTES

The statutes should empower the state authorities to take care of the following:

1. Order the installation of industrial waste treatment works in cases where "reasonable and practicable ways and means" are known and where the lack of such installation results in pollution of the receiving body of water which constitutes a menace to the public health or is prejudicial to public interests.
2. By themselves or in coöperation with industry, conduct investigations concerning industrial wastes, their treatment and disposal in cases where there are not now known "reasonable and practicable ways and means" for treatment and disposal.
3. Make scientific studies to determine the sanitary condition of water resources and their present and probable future uses to serve best the public interests.
4. Allocate water resources for various public uses so as to bring about the best and highest utilization of the several streams, lakes and parts thereof.

IN RE DEVELOPMENT OF NATURAL RESOURCES

There should be statutory authority vesting in the state authorities discretionary powers to regulate and control, so far as is reasonable and practicable, the pollution of water resources arising from the development of natural resources so as to foster simultaneously the utilization of mineral wealth and protect the streams draining such regions.

Factories can be located in suitable places, but mineral resources must be developed *in situ*.

ADMINISTRATION AND ENFORCEMENT

Such statutes, powers and duties should be administered with even-handed justice to the end that the commonwealth, its municipalities, its citizens, and its industries are benefitted, not harmed.

To that end the state authorities should offer helpful counsel, lead the way, guide and direct rather than arbitrarily issue formal orders without considering the practicability of their being carried out.

However, when in the administration of the statutes it does become necessary to invoke the police power of the state and issue a formal order, it should be so worded and in such terms that, if not obeyed and the case comes before a court for adjudication, there will be no difficulty in the Attorney General proving to the court the justice and equity of the order so that it will be sustained even upon appeal.

No action should be started that cannot be successfully finished.

Fines and imprisonment for violation of such statutes may intimidate the smaller towns and corporations but in the last analysis they are merely punitive and the end result of the enactment and enforcement should be money spent on construction, rather than paid into a public treasury and the nuisance continued.

For wilful stream pollution from non-going concerns, as for example the heedless emptying of vats in an abandoned factory, or the discharge of unsaleable milk from a receiving station, a money fine is the only redress and acts as a deterrent to such a flagrant practice.

Special Inspectors of Child Labor in Czechoslovakia

ON February 26, 1930, the Minister of Social Welfare of Czechoslovakia issued a circular to the factory inspection authorities in which he announced that a special division had been established in his ministry for better enforcement of the child labor law. The work is to be carried out by inspectors selected from the regular factory inspection staff. These government inspectors are to coöperate with the trade unions of young workers. The circular states specifically that the work of the new division will not be limited to the enforcement of labor legislation but will also occupy itself with other welfare problems of young workers.—*Lehrlingschutz, Jugend- und Berufsfürsorge*, Apr., 1930, p. 22.

PSITTACOSIS

PSITTACOSIS does not rank very high in order of numerical importance among the diseases acquired by man from the lower animals, but it stands second to none in interest from the scientific point of view.

The disease was recognized in 1879 by Ritter, who was not only a keen clinician but a shrewd observer, as he recognized the etiological significance of birds; since that time isolated cases, and more or less extensive outbreaks have occurred in most countries of western Europe as well as on this side of the Atlantic.

Our present interest springs from the epidemic which had its inception in the United States at just about the turn of the year. Many cases were traceable to parrots presented as tokens of Yuletide greetings, but they were, in fact, carriers of the disease to many, and of death to a few.

Approximately 150 cases have occurred, with 25 fatalities. It is a very safe assumption that the true figures of incidence and fatality would be higher than those given, since unless one has the clue (and recognizes it) in the shape of a bird, usually a sick one, the case will certainly pass as atypical influenza or atypical pneumonia. The newspapers have rendered excellent service in calling attention to the outbreak; indeed, without their aid, many cases, perhaps the majority of those reported, would have appeared in morbidity and mortality records under other diagnoses.

During the past few months the disease has attracted attention

in South America, England and Germany, as well as this country; in each it has taken its toll among those exposed.

Once the disease is suspected the clinical diagnosis is relatively simple. The onset with chill, headache, and fever without catarrhal symptoms is suggestive; when such manifestations are followed by physical signs in the chest indicative of pneumonia, but unaccompanied by the usual symptoms of that disease, with the symptoms insignificant or out of proportion to the physical signs, the diagnosis may be considered as established. Laboratory methods are of little value in diagnosis, save perhaps that a low leucocyte count speaks against pneumonia of the ordinary sort.

As to the bird carriers, parrots stand first, parakeets (love birds) next, and it is believed that canaries are not beyond suspicion. The presence of a bird—sick or well—should serve to put the physician and the health officer on guard. The bird usually is decidedly ill and often dies, but cases have occurred from association with birds showing little or no evidence of illness. Usually a newly acquired bird is the source of infection, though this is not always true.

The research work carried out during the present epidemic seems to exclude Nocard's bacillus (a member of the paratyphoid group) as the cause of the disease and points to a filtrable virus as the essential etiological agent.

Of great importance and interest have been the laboratory outbreaks. Infections of research workers have accounted for the death of Dr. William R. Stokes, of the Baltimore City Health Department, and of Harry B. Anderson, of the Hygienic Laboratory of the U. S. Public Health Service. The most extensive outbreak was that occurring at the Hygienic Laboratory. Eleven cases occurred, only 2 of which were due to direct exposure to infected birds. The exact mode of infection in the remaining 9 cases is unknown.

It is evident that we have in psittacosis a disease demanding much research, but the fact that the research is especially hazardous will not deter those carrying on the necessary investigations.

From the point of view of public health procedure the problem seems very simple. The individual may protect himself by refraining from keeping parrots and certain other birds, or from exposing himself to them. In the present state of our knowledge, an embargo on suspected birds seems to be the only solution, from the point of view of public health authorities, national and local, and indeed, it is a question whether all birds of the susceptible group should not be considered as coming under suspicion.

WHAT IS THE SATURATION POINT FOR CITY NOISE?

THAT noise is unavoidable where people gather themselves together in communities is a fact as ancient as the man-made institution of cities and towns, but never before in the history of the world has there been such a constant clamor as is produced in modern cities or one made up of so many startling, alarm-like elements.

To a certain extent we can and do adapt ourselves to the conditions of noise, but common experience shows that there are limits to this adaptation. Everyone who has tried to sleep through the hum of after-theater traffic interspersed with nervous tooting of horns, through the rattle of milk delivery, through the clatter of ash collection—all the noises of a city night—knows that custom does not mitigate the annoyance caused by noise. Everyone who has tried to do a piece of work in the din of adding machines, typewriters, telephone bells and office conversation knows that he is disturbed by these things—at some times more than at other times, to be sure, but nevertheless appreciably disturbed. Business firms, realizing this disturbing effect of noise on workers, willingly spent over \$3,000,000 last year in the attempt to dampen office noises and exclude street noises.

The researches of psychologists so far have been a confirmation of this common experience, usually revealing that noise has been more of a handicap to rest and to work than the average man ever suspected.

One question has not been answered in laboratories and it is doubtful if it can be answered there, where conditions are sifted of many of the elements of everyday life: What is the saturation point for city noise—the point beyond which human adaptation cannot compensate for the tax noise levies on the attention, on the energy, and on the relaxation periods?

A pragmatic answer is given in the letters sent to the Health Department over a period of years complaining of noise in the five boroughs of Greater New York. The very fact that people have written these letters after a period of suffering is an answer to the question: How much noise can individuals stand?

We say, "after a period of suffering," advisedly. A study of these letters reveals that, while one out of twenty-five may be from a crank, the other twenty-four are from sensible people who have delayed making their complaints until they could endure conditions no longer. One letter, for example, tells of night riveting that had gone on for three months before the people in a neighboring apartment house decided to complain; another from the dean of women of a leading college protested against the clangor of street traffic that had disturbed a whole semester's work in the classrooms on the exposed side of the

buildings; and school principals had figures to prove the slowing up of the whole year's work by the constant disturbance of recitations by noise from outside. So it goes through the voluminous files that house these complaints—the majority of the complaints show that stable, serious people are disturbed by noise to the point where they feel that they cannot adapt themselves to it.

It seems significant that these people should turn for help to their department of health. With an instinctive logic, they recognize noise as a health problem—a serious hindrance to their well-being and efficiency. Whether or not noise has reached its worst proportions at this time, it surely has reached a point where something must be done to give people relief from it—something more than the abating of individual noises when and as complaints are made of them.

Another thing—significant of the way the noise nuisance has projected itself into the minds of thinking people as a problem that must be solved now—is the alacrity with which the members of the New York Noise Abatement Commission entered into their work. Not one of the fourteen men invited last October to serve on this commission—and they knew they would have much hard work to do—refused to perform his patriotic task. Doctors, lawyers, builders, engineers, executives of large organizations, all had found noise a great handicap in their varied work and had already given much thought to its curbing.

The noise survey of the city, conducted by the Noise Abatement Commission during its first four months, reveals tremendous peaks of noise at certain places and at certain hours—noise that piles up as high as 94 decibels down on Cortland Street where the radio shops are congregated, and 76 decibels at many of the street corners where cross town trucking is heaviest. This approaches the 100 decibel limit, which is the point where sound is so loud that it sets the ear tingling. This would seem to be a point where continued noise creates physical discomfort.

The survey further reveals that the din of traffic cluttered streets travels up as high as the thirtieth floor of office buildings and that a full medley of city noise reaches up even higher—to the very topmost floors of isolated skyscrapers.

Perhaps we cannot truly say that the noise of the city has reached the saturation point in view of the fact that there are still oases of comparative quiet—like the Mall in Central Park, the first set-back stories of the new style skyscrapers that are protected from street noise by the sound-shadow of the out-jutting stories below, and a few residence streets in Brooklyn where the sound of baby carriage wheels is recorded by the noise testing machines used in the survey.

The fact remains that unnecessary noises surround most of the six million New Yorkers during all their working hours and most of their sleeping hours. Many people never have a chance to recover from the effects of one group of noises before they are exposed to another group. Already noises, or rather the causes of noise, are so closely interwoven with our economic and industrial life that it will take the combined ingenuity of builders, acoustical engineers, automobile builders, and lawyers to change present conditions without working hard-ship on any group in the community. Fortunately the Noise Abatement Commission is made up of men equipped by their life training to deal with the many ramifications of this modern public health problem and make New York a more comfortable, more livable city for all classes of people living in it.

CONGRESS AUTHORIZES NATIONAL INSTITUTE OF HEALTH

THE bill for a National Institute of Health, which has been pending before Congress for several years, was passed late in May, and signed by the President. This measure, which had been endorsed by the American Public Health Association, changes the name of the Hygienic Laboratory of the U. S. Public Health Service to National Institute of Health, authorizes the appropriation of \$750,000 for its expansion, permits the government to accept unconditional gifts and donations for investigations of human diseases and public health conditions, and allows qualified scientists to be appointed fellows at the newly created Institute. The bill was sponsored by Senator Joseph E. Ransdell of Louisiana. It is gratifying to know that Congress is sufficiently interested in public health, in the midst of its discussions of the tariff and other important matters, to pass this measure.

ASSOCIATION NEWS

Cathedral, Mexico City

A NINE-DAY, ALL-EXPENSE TOUR WITH 5 DAYS IN
MEXICO CITY,

FROM THURSDAY, MIDNIGHT, OCTOBER 30, TO SATURDAY, NOVEMBER 8, 1930

FOR MEMBERS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION AND
THEIR FAMILIES, FOLLOWING THE FIFTY-NINTH ANNUAL MEETING
OF THE ASSOCIATION IN FORT WORTH, TEX., OCTOBER 27 TO 30, 1930

THE Chief of the Department of Health of the Republic of Mexico, Dr. Rafael Silva, has, in the name of the department and with the approval of the President of the Republic, invited the members of the American Public Health Association to visit Mexico City following the Annual Meeting in Fort Worth, for the purpose of meeting the public health workers of Mexico and participating in a scientific program of interest to American public health work-

ers. At the same time members of the Association are invited to be the official guests of the government at a number of entertainments.

In addition, the members of the Association in San Antonio, Tex., have invited the delegates to stop over for a visit in San Antonio and to participate in a brief meeting in that city.

In order to make the acceptance of this invitation convenient for the members of the Association and to reduce the

expense, an all-expense tour on a special train has been arranged.

The preliminary itinerary and program follow:

Thursday, October 30—

10.00 P.M.—Cars open—Fort Worth

Friday, October 31—

12.30 A.M.—Lv. Fort Worth

Breakfast on train

9.00 A.M.—Ar. San Antonio

9.15 A.M.—Tour of the city, visiting
The Alamo, Medina Lake,
etc.

12.15 P.M.—Return to Hotel

12.30 P.M.—Luncheon

Afternoon—At leisure

4.00 P.M.—Lv. San Antonio

Dinner on train

8.30 P.M.—Ar. Eagle Pass

Saturday, November 1—

Breakfast on train

8.00 A.M.—Ar. Monterrey—tour of city
including El Canon,
Bishop Palace, etc.

10 30 A.M.—Lv. Monterrey

Luncheon on train

Dinner on train

Sunday, November 2—

Breakfast on train

9.00 A.M.—Ar. Mexico City

9.30 A.M.—Excursion to San Juan Teo-
tihuacan (Pyramids, Mu-
seum and Garden)

12.00 M. —Luncheon, Gruta Restaurant,
under auspices of Secre-
tary of Public Education

2.00 P.M.—Return to Mexico City

4.00 P.M.—Folklore Pageant at Centro
Venustiano Carranza
(Outdoor Theatre) under

the auspices of Federal
District of Mexico

Evening—At leisure

Monday, November 3—

9.30 A.M.—Meeting of the Delegation
with the Department of
Public Health of the Re-
public of Mexico—Assem-
bly High School Auditor-
ium or at the Department
of Public Health

PROGRAM

1. Address of Welcome—DR. RAFAEL SILVA, Chief of the Department of Public Health of Mexico
 2. Reply to Address of Welcome—A. J. CHESLEY, M.D., President of A. P. H. A., HUGH S. CUMMINGS, M.D., Surgeon General of the U. S. Public Health Service, Washington, D. C., and J. C. ANDERSON, M.D., State Health Officer of Texas
 3. History of Health in Mexico—DR. ULISES VALDES, Secretary General of the Department of Public Health.
 4. Local Public Health Work—DR. MIGUEL BUSTAMANTE, Director of Health Unit at Vera Cruz, Ver.
 5. Display of film showing public health work in Mexico
- 1.00 P.M.—Luncheon
- 4.00 P.M.—Reception and meeting of President Ortiz Rubio, Chapultepec Castle
- 9.00 P.M.—Banquet and Dance, Auspices of Department of the Central Federal District of Mexico

Tuesday, November 4—

9.30 A.M.—Scientific session

PROGRAM

1. Address—W. S. RANKIN, M.D., *Chairman*, Executive Board, A. P. H. A., Duke Endowment, Charlotte, N. C.
 2. Address—B. J. LLOYD, M.D., Pan American Sanitary Bureau, Washington, D. C.
 3. Safeguarding a City Milk Supply—H. V. CARDONA, D.V.M., Supervisor of Milk Sanitation, Department of Public Health and Welfare, Fort Worth, Tex.
- 12.00 M. —Drive to the Desierto de los leones (Desert of Lions)
Luncheon, under the auspi-
ces of the Secretary of
Public Works

Xochimilco's Floating Gardens

2.00 P.M.—Return to Mexico City, with a tour of the city, including the Cathedral, The Plaza de Toros, Chapultepec Castle (the White House of Mexico and former home of Maximilian and Carlotta), etc.

Evening—At leisure

Wednesday, November 5—

9.30 A.M.—Tour of inspection of the beautiful new buildings of the National Department of Health

12.00 M. —Depart for Xochimilco—Luncheon under auspices of Department of Public Health

3.00 P.M.—Walk in Gardens and gondola tour of canals of Xochimilco

Inspection of Mexico City Water Supply

Evening—Concert

Thursday, November 6—

The delegates will be at leisure to make their own arrangements individually or in groups for additional sight-seeing or visits to places not included in the previous four days.

8.30 P.M.—Lv. Mexico City

Friday, November 7—

7.00 A.M.—Breakfast on train

12.00 M. —Luncheon on train

6.30 P.M.—Dinner on train

Saturday, November 8—

2.00 A.M.—Ar. Eagle Pass

7.00 A.M.—Ar. San Antonio

7.15 A.M.—Breakfast on train

12.00 M. —Luncheon on train

3.30 P.M.—Ar. Fort Worth

The total cost of the tour, including all expenses from Fort Worth to Mexico City and return to Fort Worth, with stop-over in San Antonio, including sight-seeing, transportation, all meals en route and during five days in Mexico City, all side trips, and the use of pullman cars in Mexico City, is to be as follows:

1 person in upper berth—\$112.40
1 person in lower berth—\$149.90
2 persons in lower berth—\$126.15 each
2 persons in a section—\$131.15 each
3 persons in a section—\$121.55 each
2 persons in a compartment—\$169.90 each
3 persons in a compartment—\$147.40 each
2 persons in a drawing-room—\$189.90 each
3 persons in a drawing-room—\$160.75 each

Assurance has been given that the most modern equipment will be used on the special train, including observation car, maid and valet service, shower bath, dining car, baggage car and probably a radio. An individual making the trip by himself would need to spend approximately \$250 to cover the same ground.

Application for a place in the delegation should be made on the following blank, and this sent to the Executive Secretary of the Association.

Homer N. Calver, Executive Secretary,
American Public Health Association,
370 Seventh Ave., New York, N. Y.

Please reserve in the Delegation of the A. P. H. A. to Mexico City

PLACES OF INTEREST IN DELEGATES' OWN TIME

Guadalajara—This city, with a population of 180,000, is the capital of the state of Jalisco, and has an elevation of 5,200 ft. above sea level. It is the second city in size and importance in the Republic. It is known for its many fine buildings, churches and homes. In and near Guadalajara are points of interest considered some of the most attractive in the Republic, including the wonderful falls some 5 miles from the city, and Lake Chapala some 20 miles from the city. Guadalajara is an overnight ride by train from Mexico City.

Puebla—A round trip can be made to the city of Puebla by automobile or bus in one day very comfortably, over the paved highway from Mexico City some 75 miles distant. Puebla has a population of over 100,000 with an elevation of 7,100 feet above sea level. It is noted for its Cathedral and Royal Chapel. Other points of interest near Puebla include the Pyramid of Cholula, which has a direct relation to the Pyramid of San Juan Teotihuacan near Mexico City.

Cuernavaca—This is a celebrated health resort, a mecca for tourists out of Mexico City. Cuernavaca has 7,000 to 10,000 population. A magnificent new paved highway from Mexico City to Cuernavaca, 40 miles distant, leads through some of the most wonderful scenery in this area. The highway leaves the valley of Mexico and crosses the mountain range at an elevation of between 10,000 and 11,000 feet above sea level and then descends to Cuernavaca with an elevation of 4,500 feet above sea level. This city is noted for many points of interest, including the home of former Ambassador Dwight Morrow, the original Palace of Cortez, the famous Borda Gardens and the Cathedral, one of the oldest and quaintest churches in the Republic, built in 1529, also caverns and river falls nearby. The round trip from Mexico City can be made comfortably by automobile or bus in one day.

Veracruz—Population is 100,000. Veracruz is one of the oldest and most historical cities in the Republic and formerly was the chief seaport. The trip from Mexico City to Veracruz by rail is through a mountainous section with some of the most picturesque scenery,

and can be made in one day and return overnight. Veracruz has also recently inaugurated a substantial full-time health department serv-

Castle of Chapultepec

ice, jointly through the federal health service, the state health service and with the cooperation of the International Health Board. This work is being carried on under the direction of Señor Alfonso Isunza and Dr. M. E. Bustamante.

NOTE: Other trips may be arranged for those having more time to such points as the two snow capped peaks that can be seen from Mexico City at all times, namely: Popocatepetl and Ixtlaccihuatl. Popocatepetl rises 17,782 feet and The Sleeping Lady (Ixtlaccihuatl) 16,060 feet above sea level. Not to have gazed awe-struck at these peaks from various points of vantage is to have missed two of the most inspiring scenic beauties of the world.

Monterrey—The Capital of the State of Nuevo Leon has a population of 150,000. Its altitude is 1,500 feet. This center for corn, beans, garbanzas and wheat is a busy commercial city with many factories. The principal points of interest are the Government Palace; the church of San Francisco, the most interesting antique in Monterrey, erected in 1590; El Obispado (Old Bishop's Palace), built 1785, from which is obtained a wonderful panorama of the city and surrounding mountains that will long remain in the memory. Near Monterrey are the Garcia Caves and Topo Chico Hot Springs.

OTHER MEETINGS

Simultaneously with the meeting of the Association in Fort Worth, October 27-30, the following organizations will meet: American Association of School Physicians, International Society of Medical Health Officers, Conference of

State Sanitary Engineers, Texas Association of Sanitarians.

SPECIAL TRAINS

During July a letter will be sent to the entire membership regarding special train arrangements.

WESTERN BRANCH, A. P. H. A., MEETS IN SALT LAKE CITY

THAT the Western Branch of the American Public Health Association is a definitely established and functioning organization was affirmed at their first regional meeting held in Salt Lake City, Utah, June 12-14, at which a constitution and by-laws were adopted and many western public health problems considered.

The keynote of the meeting was understanding and appreciation of each other's problems in the field of public health. Making the services and experiences of each part of the western section available to every other part was urged.

Outstanding among the many excellent speeches and papers were the addresses delivered by Governor George H. Dern of Utah, President A. J. Chesley of the A. P. H. A. and President W. C. Hassler of the Western Branch, A. P. H. A.

Governor Dern welcomed the visiting members and emphasized the humanitarian aspects and monetary value of public health work. He said: "It is sometimes puzzling that states or cities should be so reluctant to give adequate financial support to their public health departments. Surely no public expenditure returns larger dividends on the investment."

Dr. Chesley spoke of the importance of interesting the entire world in our problems, and the possibilities that such coöperation offers for a world-wide program. Dr. Hassler pointed out the necessity of awakening a health consciousness on the part of our people. With the support which this would give to the public health program, the amount of work that could be done is inestimable.

About 150 public health workers from western United States, British Columbia, and Hawaii were present at the meeting. Scientific sessions were devoted to the discussion of tuberculosis,

undulant fever, tropical medicine, meningitis, training of health officers, the recent A. P. H. A. survey of Honolulu, school health education, public health nursing and preventive dentistry.

Following discussion on Rocky Mountain Spotted Fever, a permanent committee, under the chairmanship of Dr. W. F. Cogswell, Montana State Health Officer, was appointed. One session was devoted to the public health aspect of the Boulder Dam. This is the first time that consideration has been given to this phase of the Boulder Dam project in public meeting and was followed by the preparation of a resolution requesting the Secretary of the Interior to confer with the Surgeon General regarding the entire problem.

Two evening meetings of interest to the general public were held. These were presided over by Dr. H. P. Kirtley, President, Utah State Medical Society. In discussing "Utah Public Health" Dr. Shepard at the first evening session presented a striking comparison between the practice of 1665 and the present day. Dr. Langley Porter, Dean of the Medical School, University of California, San Francisco, addressed a general session on "Keeping the Family Well." He made a plea for the general practitioner of medicine and approached the question of the cost of medical care from the viewpoint of the physician and the hospital staff rather than from the usual angle of the layman.

Officers elected to carry on the work for the coming year were:

President, William C. Hassler, M.D., San Francisco

First Vice President, E. H. Hanley, M.D., Seattle

Second Vice President, George Parrish, M.D., Los Angeles

Third Vice President, T. B. Beatty, M.D., Salt Lake City

Secretary, W. P. Shepard, M.D., San Francisco

Treasurer, W. F. Higby, San Francisco

Membership in the Western Branch has grown from 125 to almost 1,100 during the past two years, 10 new active members and 26 new regional members being enrolled at this meeting. It is because of this growth that the offices of third vice president and treasurer were created.

DR. SLEMONS MICHIGAN'S NEW COMMISSIONER OF HEALTH

C. C. Slemons, M.D., Fellow of the A. P. H. A., for 20 years City Health Officer of Grand Rapids, has been appointed Commissioner of Health of the State of Michigan, to succeed the late Dr. Kiefer. Governor Fred Green could have made no wiser selection from the available persons in the State of Michigan. Dr. Slemons is a graduate of the Detroit College of Medicine and the University of Illinois Medical School. He has been intimately associated with national and state public health work. He has for 11 years been a member of the State Advisory Council on public health. Dr. Slemons served on the Governing Council of the Association from 1921 to 1927.

DEATH OF SAMUEL M. HEULINGS

Samuel M. Heulings of Haddonfield, N. J., died at his residence, May 15, at the age of 70.

Mr. Heulings had a long life of useful endeavor devoted to improving and safeguarding public milk supplies. He was a consulting dairy engineer of international reputation and was identified with the development of the first machinery used for the commercial pas-

teurizing and handling of milk in this country.

For a number of years Mr. Heulings manufactured high class dairy equipment at Haddonfield, N. J.; later he was connected with the Sheffield Farms Corporation in New York City and for many years directed the construction and operation of machinery used to process a large portion of the milk supply of New York City. In his work he was always closely associated with municipal health departments and his opinion was highly respected in all matters concerning milk improvement. He has steadfastly advocated the use of the highest standards of safety in pasteurizing milk and has been a ruthless opponent to any and all who have suggested lower standards. As an inventor he has given the dairy industry many useful devices. He is the author of several important contributions to the literature on dairy topics.

During the last few years of his life Mr. Heulings has been consultant to the Lower Merion Township Board of Health on Milk Control matters. At the time of his death he was engaged in the invention and construction of a pasteurizer which he had hoped would enable the processing of milk in a manner far superior to methods used heretofore. Mr. Heulings was a member of the American Society of Mechanical Engineers and a Charter Fellow of the American Public Health Association, elected in 1922, having been a member since 1917. He served for some years on the Committee on Milk Supply of the Sanitary Engineering Section of the A. P. H. A.

GERMAN HYGIENE MUSEUM, DRESDEN

THE opening of the new building for the German Hygiene Museum, which has been contemplated since 1911, brings to maturity the plan of presenting in actual or symbolic form, by a series of exhibits, the present-day

knowledge and accomplishments of hygiene, and at the same time shows the widening scope of the Hygiene Museum and its work.

The Museum is also an inspiration center to act as the starting point for a

movement to create opportunities everywhere for permanent instruction in hygiene, thus realizing the ideals of Karl August Lingner, who was a pioneer in exhibition work, and who was responsible to a great extent for the 1911 International Hygiene Exhibition.

With the aid of the German Reich, the Freestate of Saxony, and the City of Dresden, a suitable home has been erected for the Museum on a beautiful central site in Dresden, in the vicinity of the large athletic fields of the Grosser Garten. The foundation stone of the Museum was laid on October 8, 1927, and on May 17, 1930, the new building was dedicated and opened to the public. This also marked the opening of the 1930 International Hygiene Exhibition. For the first time a number of new specimens and groups are shown representing both the latest scientific researches and the development of exhibition technic.

The territory covered by the exposition extends over 120 acres. The center is occupied by the new building constructed by the architect Dr. Wilhelm Kreis. The center of the collections, as in 1911, is the exhibit "The Man" showing the anatomy and physiology of the human body by pictures, models,

preparations, and other devices. Part of this exhibit is the "Transparent Man," a special method of making translucent the tissues of the body, the blood vessels, the skin formation and structure, the respiratory organs—showing lung tissues, etc. Around this are various other groups.

The scientific director of the Museum, Professor Dr. Martin Vogel, is particularly proud of the exhibit which constitutes the department of "Public Health Education." The industrial exhibit also contains many attractive features, while a special exhibit on the "Hospital" has its location in a spacious building covering 1½ acres of ground.

Many countries are represented in the international part of the exhibit.

Ninety-two members of the A. P. H. A. sailed on the S.S. Adriatic from New York on June 14. They will spend about a week in England, and stop at Brussels, Cologne, Wiesbaden and Berlin before reaching Dresden on July 5. Four days will be spent in Dresden. Quite an extended trip will be taken from there—visiting several German cities, viewing the Passion Play at Oberammergau, then going on to Switzerland and France.

NEW MEMBERS

Health Officers Section

Milton F. Arnholt, M.D., Lincoln, Nebr., Superintendent of Health

Dr. Juan B. Ascanio, Caracas, Venezuela, General Inspector, National Public Health Service (Assoc.)

Atticus G. Blanton, M.D., Sonora, Tex., City and County Health Officer

Lawrence T. Browning, M.D., Kingwood, W. Va., Director, Preston County Health Dept.

Howard L. Darby, D.V.S., Ft. Worth, Tex., Inspector in Charge, U. S. Bureau of Animal Industry Tuberculosis Eradication

Leo P. FitzGerald, M.D., University City, Mo., Health Commissioner

James H. Flynn, M.D., Troy, N. Y., Commissioner of Health

W. H. Ford, M.D., Sudan, Tex., City Health Physician

Joseph P. Franklin, M.D., Cumberland, Md., County and Deputy State Health Officer

Zalmon E. Funk, M.D., Santa Rosa, N. M., Guadalupe County Health Officer

Menno Hostetler, M.D., Wichita, Kans., County Health Officer

Carl C. Irick, M.D., Webster Groves, Mo., Health Commissioner

Marshall T. Knox, M.D., Cleburne, Tex., City Health Officer

S. R. McKelvey, M.D., Denver, Colo., Executive Secretary, State Board of Health

A. R. Matthews, Mule Shoe, Tex., County Health Officer

Louis O. Obrock, M.D., Clayton, Mo., Health Officer, St. Louis County

John B. Setzler, M.D., Columbia, S. C., Director, Richland County Health Unit

Edward H. Trowbridge, M.D., Worcester,

Mass., Chairman, City Board of Health
 Dr. Jerry E. Vanderpool, Walla Walla, Wash.,
 Health Officer

Laboratory Section

O. C. Gerhardt, Houston, Tex., Chemist and
 Bacteriologist, Phenix Dairy
 Marshall W. Jennison, S.B., Cambridge, Mass.,
 Teaching Bacteriology, Massachusetts Insti-
 tute of Technology
 Joseph J. Reid, D.V.M., Ft. Worth, Tex., Lab-
 oratory Director, Livestock Sanitary Com-
 mission
 James N. Roche, Ph.D., Pittsburgh, Pa., Re-
 search Worker, Koppers Company
 W. S. Stanley, Houston, Tex., Chemist, Sewage
 Disposal Plants

Vital Statistics Section

Joseph P. Yaffe, M.D., Boston, Mass., School
 Physician

Public Health Engineering Section

John W. Carey, University City, Mo., Super-
 visor of Sanitation
 G. C. Carvajol, San Antonio, Tex., Chief Milk
 Inspector
 F. E. Devlin, Amarillo, Tex., Consulting Engi-
 neer, Water and Sewage Purification Prac-
 tice
 J. E. Foster, Houston, Tex., Production Man-
 ager, Phenix Dairy (Assoc.)
 Fred B. Green, Austin, Tex., Supervisor, Milk
 Sanitation, State Department of Health

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Providence, R. I., Survey—The attention of the public health worker has for a long time been focused upon Providence, R. I., because of the unusual piece of health work being carried on there under the direction of Charles V. Chapin, M.D. Therefore, it is particularly interesting that a health and hospital survey has been made. The survey was carried on by James Wallace, M.D., under the auspices of the Committee on Administrative Practice of the A. P. H. A. A report of 314 pages has been published in which are set forth many of the remarkable contributions to public health made by Providence through Dr. Chapin, and Edwin M. Snow, M.D., his predecessor.

This city has been credited with being a pioneer in several fields of public health administration, largely due to the commanding influence of Dr. Chapin, who has been the Superintendent of Health for 46 years. In fact, since the organization of the Department of Health in 1856 there have been only two health officers in Providence, Dr. Snow having served for 28 years.

... These records are remarkable for the two physicians in that they were able to give such long continuous service, and remarkable for the city that there has been so little political interference with the office, and that it has been fortunate in having administrative officers who have been spared to it and remained with it in all the changing conditions incident to three-quarters of a century of a city's life.

Providence was the first city in this country to establish, in 1888, a municipal public health laboratory. In 1893 the first experiments in filtering water by municipal filtration were made here. Providence was the first city to discontinue, in 1905, fumigation as a form of

terminal disinfection. This city was one of the first in the United States to make vaccination against smallpox a qualification for school enrollment. It has been a requirement for school attendance since the year 1856. It is stated that Providence was the first city in the country to establish, in 1908, an open air school for children needing education under special protective conditions.

Based on the *Appraisal Form for City Health Work* (3d ed.), of a possible 1,000 points Providence attained a score of 817.2. There is a general uniformity of high attainment in all of the recognized activities, no one of which scores less than 50 per cent. With the exception of preschool hygiene, food and milk control, public health instruction, cancer and heart disease, all of the activities rated 80 per cent or better. The staff of the Department of Health consists of 61 persons, 34 of whom are full-time and 27 part-time. In addition to the Superintendent of Health there are 2 deputy superintendents, 16 nurses, 5 inspectors, 2 technicians, 7 clerks, 1 automobile driver; and a part-time personnel consisting of 12 clinic physicians, 7 physicians for sick poor and private schools, 2 dentists, 1 technician and 3 clerks. There is no division of venereal disease control, this work being carried on by the State Department of Health. The City Department of Health with its 16 nurses performs only a part of the public health nursing work, as this work is supported by the District Nursing Association employing 72 nurses and the public school staff of 18 nurses. There is no division of the department dealing with tuberculosis. This is partly a state

function and partly a function of a voluntary agency, the Providence Tuberculosis League.

Among the general recommendations made by the Survey Committee is one for better financial support of the City Department of Health. Despite a low per capita appropriation for health, Providence has done a splendid job in health conservation. Another recommendation was that a properly planned program of popular health instruction be inaugurated. To the epidemiologist the details of the control practices as performed in Providence should be of special interest. It is not the general practice passively to immunize by giving diphtheria antitoxin to all susceptible household contacts. These are kept under observation and if they give any indication of developing diphtheria they are given a full therapeutic dose.—James Wallace, M.D., *A Survey and Appraisal of the Health Activities of Providence, 1929*. Published by Providence Community Fund.

Municipal Expenditures for Public Health—Using the tabulations prepared for *Public Health Bulletin No. 164* giving the official expenditures for the various divisions of public health procedure, an endeavor has been made to ascertain any possible correlation between a reduction of infant mortality in large American cities and amounts of money expended by official agencies for various health functions. As there exists no uniformity of bookkeeping for health departments it is extremely difficult to make comparisons by function.

Under these limitations there cannot be shown statistically any direct relation between the per capita expenditures and infant mortality rates, on the basis of geographical correlation for a single year. The desirability of a study using reliable figures for a series of years immediately suggests itself. Thus we might ascertain whether increasing per capita expenditures for various health services has a definite effect upon the general trend of infant mortality.—Richard A. Bolt, *Municipal Expenditures for Public Health, J. Hyg.*, 11, 601 (May), 1930.

Rural Health Service—At the beginning of the present calendar year there were 505 counties or districts with local health service under whole-time health officers. Eighty-eight per cent of these were receiving aid from the state health department, U. S. Public Health Service, or the Rockefeller Foundation. During 1929, whole-time health service for counties was established in 47 units and was discontinued in 9. The largest gain in one state was that of 15 in Tennessee. For per cent of rural population served, Alabama leads with 80 followed by Maryland, Ohio, South Carolina, Louisiana, and North Carolina, each exceeding 50 per cent. The rural population of the United States in 1920 was 51,406,017 of which 24 per cent is now served with whole-time health departments.—L. L. Lumsden, *Extent of Rural Health Service in the United States, 1926-1930, Pub. Health Rep.*, 45, 1065 (May 9), 1930.

LABORATORY

C. C. YOUNG, D. P. H.

DESCRIPTION OF A NEW MECHANICAL DISINTEGRATOR

E. W. SCHULTZ, M. D., F. A. P. H. A., AND F. D. BANHAM

Stanford University, Calif.

INVESTIGATORS working with filterable viruses appreciate how much time may be consumed in reducing virus tissues to a finely divided physical state, a task generally carried out by hand with the aid of a mortar and pestle. This method of grinding tissues is not only comparatively inefficient, but exceedingly monotonous and tiring. In order to overcome these objections, we designed a machine whereby the mortar and pestle could be operated mechanically. This has proved so satisfactory that we offer a brief description of it for the benefit of those interested.

Figure I gives a top and Figure II a lateral view of the machine. The machine proper is fastened to a metal base (1). It consists of a suitable cast iron pedestal (2), provided with a thrust bearing (7), into which is fitted a shaft (6), which passes through into the

grinding chamber and bears at its upper end a driving disc (8) provided with

FIGURE II

several eccentrically placed apertures (9). The shaft is driven by means of worm gear (10), which engages with a worm (11), attached to the horizontal shaft (12) of an electric motor (13).

Within the grinding chamber a platen (14) is movably positioned above disc (8) by means of a pin (15) which fits into one of the eccentric apertures (9). The platen (14) is provided with a bifurcated end (16), which engages with a fixed pin (17) attached to the pedestal (2). The mortar may be fixed in position on the platen by means of rubber covered metal fingers extending upward from the platen (14).

The pestle (26) is held in position by

FIGURE I

means of a round flexible metal arm (23) provided with a clamp (24), operated with a thumb screw (25). The metal arm (23) is fastened by means of a special clamp (22) to a vertical triangular rod (21) fixed to the pedestal (2).

The mechanism described imparts to the platen holding the mortar an eccentric motion. By thus moving the mortar the pestle is brought into essentially the same operable relationship with the mortar as when the grinding process is carried out by hand. When desirable,

grinding may be carried on in a closed chamber (3), which may be entered by means of a hinged lid, provided with a glass window to facilitate inspection of the material while the machine is in operation.

The machine described should not only prove useful in grinding virus tissues, but also in grinding most substances that are commonly disintegrated by means of a mortar and pestle.

The device has been patented and arrangements are being completed for its manufacture.

ELECTRIC KJELDAHL NITROGEN WITHOUT FUME HOOD

W. D. STOVALL, M. D., F. A. P. H. A., AND M. STARR NICHOLS,
PH. D., F. A. P. H. A.

State Laboratory of Hygiene, Madison, Wis.

AN electric Kjeldahl nitrogen apparatus is herein described which is very convenient and satisfactory. We have used it for nearly two years and are able to make nitrogen determinations on various kinds of waters, sewage, effluents and trade wastes accurately and rapidly.

The general arrangement of the apparatus is shown in Figure I.

The still and digester were designed and constructed at the Service Department of the University of Wisconsin. The structural frame work was built in the form of brackets from 1" x 1/8" angle iron welded together, which were then securely fastened to the wall by means of bolts. These brackets were designed to receive and hold securely the various parts of the two pieces of apparatus. The switch box supports were made from a length of heavy galvanized sheeting shaped to fit the switches and form an integral part of the brackets.

tops are employed for heating the flasks in each piece of equipment. These were set in place on an angle iron shelf which is a part of the bracket. Each heating unit requires 0.6 K.W.H. of current. Four service leads from a service switch box were installed, each carrying 30 amperes of 110 volt alternating current. Each heating unit is controlled by an ordinary snap switch. The advantages of electric heating are even temperature, low fire hazard, and ease of operation and maintenance.

The distillation apparatus is provided with an automatic signal which rings a buzzer when the proper quantity of distillate is received in the flasks. To accomplish this the extreme right hand flask, Figure I, is counter balanced so that a given weight of distillate will make electric contact and ring the buzzer. The distillation rate is so constant that all flasks are filled at the same rate as the signal flask. Aside from the safety factor the analyst has no watching to do while distillation is in progress and is free to do other tests.

ELECTRIC EQUIPMENT

Gilmer heating units with hollowed

FIGURE I

THE STILL CONDENSER

The condenser was made from heavy copper sheeting in the form of a rectangular box open at the top—50" long, 24" high and 3" wide. The condenser tubes were made of block tin 7/16" outside diameter, with 1/16" wall, each 36" long extending below the tank for receiver flask connection and above tank for flask connection. They were soldered in the bottom of the tank and supported by cross arm at the top. Each tube at bend for flask connection was surrounded by a steel spring to prevent sharp bends. The copper tank was reinforced in the central part to prevent bulging. Water is connected for cooling to the bottom of one end, with a waste pipe connected with sewer at the top of the other end.

THE FUME ELIMINATOR

The fume suction tube is modelled after one described by Hastings, Fred, and Peterson (1927)¹ but with some modifications which we believe to be im-

provements. The main suction tube is of 1½" lead pipe of approximately ¼"

(A) Sketch of Gas Suction apparatus.

(B) Cross Section of one suction tube.

(C) Same as (B) but with Kjeldahl flask in place. Note sliding lead stopper

FIGURE II

wall. The essential parts of this apparatus are shown in Figure II. The construction immediately under the water jet permits the trapping of air and fumes as the water emerges from the slanting orifices. The flask connections are wiped into holes made in the main lead pipe. These side branches are of $\frac{3}{8}$ " lead pipe with $\frac{3}{16}$ " wall and are fitted with a sliding lead stopper as shown in (B), Figure II. In (C), Fig-

ure II, the flask is shown in place with the flange of the stopper resting on the lip of the flask. It is necessary that the flange of the stopper fit rather closely but the slight variation in the size of the neck of standard Pyrex flasks has offered no difficulty with our apparatus.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Vital Statistics for England and Wales, 1929—The Registrar General's report of vital statistics for 1929 gave a birth rate of 16.3 per 1,000 population and a death rate of 13.4 per 1,000 population. Communicable disease death rates per 1,000 population were: diphtheria, 0.08; measles, 0.74; typhoid fever, 0.01; and whooping cough, 0.15. The birth rate for London was 15.7 and the death rate 13.8 but these rates were for civilians only.—*Pub. Health Rep.*, 45: 754 (Apr. 4), 1930.

Vital Statistics for Scotland, 1929—The Registrar General of Scotland reported the number of deaths registered in 1929 as 70,917, giving a rate of 14.5 per 1,000 population. There were 92,876 births, a rate of 19.0 per 1,000 population. Marriages numbered 32,992 and deaths under 1 year, 8,058.—*Pub. Health Rep.*, 45: 755 (Apr. 4), 1930.

Vital Statistics for Irish Free State, 1929—The estimated population of the Irish Free State in 1929 was 2,971,992. There were 58,342 births, giving a birth rate of 19.8 per 1,000 population; and 42,974 deaths, a mortality of 14.6. Deaths from principal

causes of death were: cancer, 3,016; pulmonary tuberculosis, 3,034; influenza, 1,629; diphtheria, 292; measles, 134; scarlet fever, 60; typhoid fever, 78; whooping cough, 378; and violence, 924.—*Pub. Health Rep.*, 45: 755 (Apr. 4), 1930.

Age-Sex-Seasonal Incidence of Certain Diseases in Children—The records of nearly 2,500 patients from birth to 13 years of age who were admitted to the Hospital for Sick Children during the past 5 years and about 5,000 records obtained from the Toronto Department of Public Health were examined to determine the age, sex, and seasonal incidence in various diseases. A pronounced age incidence was observed in certain diseases. Thus, of 351 cases of endocarditis only 7 were in patients less than 4 years of age; of 108 patients with rheumatic fever, only 1 was less than 3 years of age. Almost 70 per cent of the 48 infants with scurvy were from 6 to 12 months old and only 2 were more than 2 years old. The youngest patient with tetany was 8 weeks old and over 75 per cent of the patients were from 4 to 12 months old. The age incidence of intussusception approximated

that of tetany in that 79 per cent of the patients were also from 4 to 12 months of age. In hemorrhagic disease of newborn infants, the latest time of onset was after the 10th day. There were only 21 patients with acrodynia and the age of the patients varied from 8 to 23 months.

In the majority of diseases considered, it was found that males constituted no less than 60 per cent of the total patients were affected. In the cases of pyloric stenosis, 82 per cent of the patients were males and in tetany male patients accounted for 68 per cent of the total. Pyelitis and primary peritonitis occurred predominantly in females, no less than 80 per cent of the patients with pyelitis and 75 per cent of the patients with primary peritonitis being females. Endocarditis, chorea, whooping cough, and typhoid were the only other diseases seen more frequently in females than in males.

Tetany and anterior poliomyelitis showed marked seasonal incidence. Retropharyngeal abscess, nephritis, erysipelas, primary peritonitis, and acute appendicitis occurred somewhat more frequently during the winter and spring months. Pyelitis, intussusception and pyloric stenosis, on the other hand, were noted more frequently during the summer. A slight but definite seasonal predominance was found with hemorrhagic diseases of the new-born, purpura, chicken pox, scarlet fever, measles and asthma.—F. F. Tisdall, *et al.*, *Am. J. Dis. Child.*, 39: 163–173 (Jan.), 1930.

The Homicide Record for 1929—The United States has the highest homicide death rate of any large country in the world. In 1900, the homicide death rate of 31 American cities with comparable returns was 5.1 per 100,000 population; in 1919, the rate reached 9.1; and 10 years later, in 1929, the rate was 10.1.

A detailed record for 141 American

cities for 1929, with a total population of about 38,000,000, showed 3,993 deaths from homicide, or a rate of 10.5 per 100,000. Memphis, Tenn., Birmingham, Ala., and Atlanta, Ga., showed the highest homicide rates for 1929, 66.8, 51.3 and 51.0 respectively. All of these cities have a relatively large colored population among which the homicide rate is persistently higher than among whites. The proportion of homicide deaths by firearms was 74.2 in New Orleans, 72.6 in Birmingham and 76.8 in Memphis compared to 48 per cent in Boston. The economic aspects of the homicide record are emphasized in the average age at death of the victims; for Memphis, 1924–1928, 31.7 years; Birmingham, 1927–1929, 31.6 years; New Orleans, 1920–1926, 31.3 years, and Boston, 1920–1929, 31.6 years.

The homicide rate for 13 leading cities of Canada for the period 1918 to 1928 decreased from 2.7 per 100,000 at the beginning of the period to 1.7 at the end. For 1928, the homicide death rate of Edmonton was 2.6 per 100,000; Montreal, 1.4; Ottawa, 0.18; Saskatoon, 2.8; Toronto, 2.7; Vancouver, 2.3; Windsor, 3.8, and Winnipeg, 2.5. Brantford, Calgary, Hamilton, London and Victoria had no homicides. The number of homicide deaths in the entire Dominion was 124, which, on the basis of 9,240,000 population, gives a rate of 1.3 per 100,000. For England and Wales for 1928, the homicide death rate was only 0.5 per 100,000, or precisely the same as 10 years ago. For the U.S. Registration Area for 1927, the homicide death rate was 8.7 and for 1928, 8.8.

The enforcement of prohibition has brought into existence an organization of crime and criminals. Constant attention has been directed toward Chicago as the center of organized crime, yet the homicide death rate for Chicago for 1929 was 12.7 per 100,000 or not

much above the average for the country at large. New York City had a rate of 7.1 per 100,000 or decidedly below the average of the whole country. Philadelphia had a rate of 8.8 in 1928, declining to 8.4 in 1929, or both years below the average. The rate for Detroit increased from 16.5 to 18.6. This is in marked contrast to the low rate for Windsor, Canada, which in 1928 was only 3.8, although the city is right across the river from Detroit.—Frederick L. Hoffman, *Spectator*, 124: 3, 18–19, 21 (Mar. 20), 1930.

Insured of Metropolitan Life Insurance Company—Never before during the first quarter of any year have health conditions been as good as have prevailed during the winter months of 1930. This is clearly shown by the mortality experience of approximately 19,000,000 persons who are insured in the industrial department of the Metropolitan Life Insurance Company. Comparison with the figures for the like period of 1929 shows marked reductions, for both white and colored policy holders, in the death rates for practically all of the important causes of death. Some improvement was expected, it is true, as there has been no wide prevalence this year of any of the epidemic diseases, whereas last year's first quarter health conditions were the worst experienced during the entire decade, owing to the epidemic of influenza which reached its height late in January, 1929.

The outstanding item again this year is the reduction in the death rate for tuberculosis. At the end of the first quarter, the death rate among white policy holders was only 65.3 per 100,000, a reduction of 10.3 per cent from the lowest figure that had previously

been recorded in the corresponding period. Among the colored, the death rate was 207.8, marking a drop of 4.6 per cent from the lowest previous figure.

With the exception of scarlet fever, all of the principal epidemic diseases of childhood have shown reduced mortality as compared with the winters of both 1929 and 1928. The most noteworthy drop is that for diphtheria. All indications point to a new minimum death rate for this disease this year.

An encouraging item is a pronounced drop in the death rate among white persons for cancer. If this persists (which is by no means assured), 1930 will be the first year since 1924 to show any interruption in the steadily rising mortality from malignant growths.

The largest decreases in the death rate, as compared with the early part of last year, have been those for influenza and pneumonia; but there have also been more or less marked declines for diabetes, cardiac diseases, diarrheal complaints, chronic nephritis, and puerperal conditions. Deaths from alcoholism dropped from 175, in the first quarter of 1929, to 155 in the like period of the current year; and the death rate declined from 3.8 per 100,000 to 3.3, a decrease of 13.2 per cent.

Suicides and homicides have been a little more frequent than in the early months of last year. The death rate for accidents, as a group, is practically unchanged. Automobile fatalities, on the other hand, have gone on increasing among both white and colored policy holders. Unless marked improvement takes place later in the year the death rate for this cause will be considerably in excess of the previous maximum, recorded only last year.—*Stat. Bull.*, Met. Life Ins. Co., 11: 1–4 (Apr.), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Bacteria of the Coli Group in the Intestines of Birds and Their Importance in the Fecal Pollution of Water—The author examined 74 birds of four groups—domestic land birds, domestic water birds, wild land birds, and wild water fowl. In 37 birds coli bacteria were detected. There were 46 strains which fermented lactose; 3 of these were not indol-forming; there were also 7 para-coli strains which were not lactose-fermenters. The absence of coli bacteria in the intestines of birds or fish can be traced to the purity of their environment and nourishment. No coli bacteria were found in the water of a mountain lake inhabited by ducks and snipe, but a passing flock of ducks polluted a pure water reservoir in Los Angeles with coli bacteria. Of the 46 strains of coli-like bacteria cultivated by the author, 78 per cent were fecal, 22 per cent showed signs of transition to *B. aerogenes*, and only 2 per cent were *B. aerogenes*. The conclusion is reached that *B. coli* is not necessarily present in the intestines of birds, but is present when conditions of life or nourishment bring birds in contact with men or animals. The possibility of the pollution of pure water by wild birds must therefore not be disregarded.—Minkewitsch, *Ztschr. f. Hyg. u. Infektionskrankh.*, 110: 506, 1929; *Tech. Gemeindebl.*, 33: 20, 1930. (From Papers of Water Pollution Research Board, England.)

Successive Separation in Sewage Disposal Systems—The author deals with the development and operation of various forms of sewage disposal apparatus. The composition of the average sewage which the various forms of

apparatus are designed to render stable, inoffensive and harmless is given. Two successive separations, screening and settling, are present in almost every form of apparatus.

The development of designs of tank treatment along three distinct lines of thought is fully discussed. These lines are (1) the liquefaction of the greatest possible amount of solid and its mechanical separation in single storied tanks primarily designed for maximum liquefaction; (2) the mechanical separation of as much solid as possible in two storied tanks with maximum liquefaction of the separated solids in the lower tank; (3) the maximum separation of solids in plain sedimentation tanks without any deliberate intention of liquefaction.

The first is a development of Cameron's septic tank, and has been rigorously followed in India. The second is exemplified in the Imhoff or Emscher and Travis hydrolytic tanks. The third is developed to an advanced stage at Birmingham. The essential features of all the processes are given, together with charts showing chains of successive separations in the ordinary Imhoff, single Travis, Birmingham, septic tank and filter, Croydon and Ideal Systems. The reduction of the size of the lower chambers with corner settling pockets is advised.

The author sketches the ideal installation based on the successive separation of solids from liquids and removal at each stage as fast as they are separated. The system consists of screening, grit catching, preliminary settling of sludge, sludge digestion, preliminary bio-aeration treatment, final settlement and

sludge drying. The ideal plant contains ten separations, eight of which are successive in one chain, and two in another.—F. C. Temple, *J. Inst. Munic. Co., Eng., Lond.*, 56: 549, 1929. (From Papers of Water Pollution Research Board, England.)

Activated Sludge Process for Sewage Disposal—This is a report of a paper delivered at a meeting of the Liverpool Section of the Society of Chemical Industry. It had been established by investigation that colloids in sewage, when free from the effect of electrolytes, had an iso-electric point at a pH of 4.6; below this they were electro-positive and above it electro-negative. Electrolytes moved the iso-electric point toward greater pH. In ordinary sewage with a pH of 7.4 the colloids were electro-negative.

The mechanism of the activated sludge process was discussed and it was suggested that the intense bacterial activity so enhanced the electro-negative charge on the sludge that by virtue of the great difference in the charge it acted on the colloids as an electro-negative suspension would on electro-positive colloids.

It was suggested that greater efficiency might be gained for the process by maintaining the sewage at a pH of about 5.8 during the treatment, as the colloids would then be electro-positive and the velocity of coagulation would be increased. A method of preparing activated sludge for starting up a new plant is suggested.—E. C. C. Baly, *Chem. Age*, 1930, 22, 78. (From Papers of Water Pollution Research Board, England.)

Power Gas from Sewage Sludge—The crude sludge from the Birmingham, Tame, and Rea District Drainage Board Works is pumped to the primary digestion tanks at the Saltley works where it is retained for 3 months and

then pumped to the secondary digestion tanks and thence after 2 months' retention to drying beds. A gas composed of 67 per cent methane, 30 per cent carbon dioxide and 3 per cent nitrogen, and having a calorific value of about 625 B.T.U. per cu. ft., is produced. Sludge gas drives a 34 h.p. gas engine at the Colehall works. The results of an investigation made at this plant to determine what amount of power might be expected from the sludge available at the Saltley works are tabulated. A vertical gas engine, alternator and floating gas collectors were consequently installed at Saltley.

Details are given of the floating gas collectors, which consist of reinforced concrete rafts with vertical sides and pyramids through which the gas is drawn. The estimated total available output is 10 million h.p. hours per annum, which is about five times the Board's present requirement.—Anon., *Canad. Eng.*, 57: 816, 1929. (From Papers of Water Pollution Research Board, England.)

Studies on Yellow Fever in South America. Transmission Experiments with *Aedes Aegypti*—Batches of *Aedes aegypti* which had fed on monkeys in the early febrile stage of yellow fever and subsequently passed the accepted incubation period failed to transmit the disease to normal monkeys in 50 per cent of the experiments. Over 80 per cent of blood transfers during this same period were successful.

Monkeys failing to show fever following mosquito bites later proved resistant to blood or tissue inoculations containing virus.

From these experiments arises the possibility of a natural development of immunity in man where ill defined cases of yellow fever exist.—Nelson C. Davis and Raymond C. Shannon, *J. Exper. Med.*, 50, 6: 793–801 (Dec. 1), 1929. Abstr. H. A. Johnson.

Studies on Yellow Fever in South America. Transmission Experiments with Certain Species of *Culex* and *Aedes*—Experiments were made to determine the possibility of transmission of yellow fever to monkeys both by the bites and by injection of ground-up mosquitoes of the species *C. fatigans*, *Aedes scapularis*, *Aedes serratus*, and *Aedes taeniorhynchus*.

Aedes scapularis was the only species found capable of transmitting the virus by bite. Injection of ground-up *Aedes serratus* and *Aedes taeniorhynchus* seemed to produce light attacks of yellow fever in the monkeys. There was no evidence that the disease could be transmitted by *C. fatigans* in either manner, although monkeys bitten by this species appeared to have acquired a relative immunity to the disease.—Nelson C. Davis and Raymond C. Shannon, *J. Exper. Med.*, 50, 6: 803–808 (Dec. 1), 1929. Abstr. H. A. Johnson.

Enumeration of the Anaerobic Sulphite Reducing Bacteria and the Significance of Their Presence in Water—The writer gives a very able discussion of this subject and in his summary reduces the results of his work to a small space. He concludes that anaerobic sulphite reducing bacteria, both obligatory and facultative, are numerous in feces of man, less numerous in the excreta of the horse and cow, and of varying extent in that of gulls; in feces sulphite reducers are more numerous in the vegetative states than as spores; the presence of these organisms

in water indicates objectionable contamination and that the preponderance of vegetative forms shows such contamination to be recent. Vegetative forms of sulphite reducers were more resistant to unnatural conditions, including the presence of chlorine, than *B. coli*.

There is now no certainty that all sulphite reducers are non-pathogenic, but since they are likely to be of objectionable origin their presence in drinking water is to be deprecated.—B. A. Adams, *Water and Water Eng.*, 31, 369: 412–415 (Sept. 20), 1929.

A Study of the Possibilities of Transmitting Yellow Fever by Means of Stegomyia Excreta—(Title briefed.) Inoculation of *Macacus rhesus* with excreta of infected *Aedes aegypti* with consequent production of yellow fever definitely showed that yellow fever virus is present in excreta of infected aedes.

From 5 to 7 days following a blood meal on infected monkeys, yellow fever virus was found in aedes excreta. Male aedes placed with infected females were found 12 days later to have acquired yellow fever virus. Female aedes left in contact with infected males for 17 days acquired the infection as shown by inoculating monkeys.

The above results show the possibility of spreading yellow fever virus among mosquitoes without a blood meal or human host.—H. de Beaurepaire Aragao and A. da Costa Lima, *Trop. Dis. Bull.*, 26, 12: 1001 (Dec.), 1929. Abstr. H. A. Johnson.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Toxicity of Dichloro-Difluoro Methane: A New Refrigerant—The contemplated use of the substance named in the title for domestic and commercial refrigeration and in air conditioning public buildings and possibly homes, has caused the Experiment Station to investigate the possible health hazards of the new product. The present is a brief report giving the results of studies on animals exposed for 7 to 8 hours daily for a period of approximately 12 weeks to breathing 20 per cent by volume of the vapors of the substance in air. This percentage was chosen because it had been found to produce distinct symptoms at this concentration although no indication of acute poisoning; also, such percentage represents an abnormally high value from the viewpoint of contamination of air by gases and vapors, but not high enough to reduce the oxygen content to an asphyxiating degree.

A description of the apparatus used with an accompanying diagram and tables showing the results of tests, accompany the article.

Dogs, monkeys, and guinea pigs were used in the prolonged experiment above mentioned. Dichloro-difluoro methane was found to produce mild to moderate tremor in dogs and monkeys with a gait resembling alcoholic ataxia but not unconsciousness. A tolerance was developed, as manifested by a decrease in symptoms. Guinea pigs showed no significant symptoms. Weight, blood test, autopsy findings, and pregnancy were not materially affected. No fatalities occurred among the dogs and monkeys. Those few which occurred among guinea pigs apparently had no relation to exposure.

The investigation has shown that at least 20 per cent dichloro-difluoro methane vapor can be repeatedly withstood for 7 to 8 hours daily, with but an occurrence of temporary symptoms and without signs of cumulative or permanent deleterious effects. The compound is therefore placed in the class of practically non-toxic gases (a table of toxic gases is given on an accompanying page).—R. R. Sayers, W. P. Yant, John Chornyak, and H. W. Shoaf, U. S. Bureau of Mines, *R. I. 3013*, May, 1930, 14 pp.

Warning Agents for Methyl Chloride in Refrigeration Systems—A research was made to find a warning agent for admixture with methyl chloride so powerful that if a leak should occur from a methyl chloride refrigerating machine, those present would receive an unmistakable warning before dangerous concentrations of methyl chloride and warning agent in the air were reached. The requirements, factors opposing and favoring irritants and odorants, the sizes of leaks which agents must warn against, are all considered.

The principal content of the bulletin summarizes the experimental data secured from testing a large number of substances with the general conclusion or unanimous opinion of the chemists who were connected with the problem that although several substances are very good warning agents in some respects, each has some objectionable properties. At present acrolein appears to be the best, but among other good agents are sulphur dioxide, allyl alcohol, butyl mercaptan, ethyl mercaptan, dimethyl sulphide, and chloropicrin. Preliminary tests also showed that a consid-

erable number of substances (named) were rejected for one reason or another.—The Roessler & Hasslacher Chemical Co., Niagara Falls, N. Y., Mar. 1, 1930, 31 pp.

Observations on the Possibility of Methyl Chloride Poisoning by Ingestion with Food and Water—Summary as follows:

1. No apparent signs of poisoning were caused by the average daily ingestion on 4 consecutive days of 550 gm. of ground raw beef or 200 c.c. of milk that had been exposed 15 to 75 hours to 100 per cent methyl-chloride vapor at 35° F.

2. No apparent symptoms of poisoning or changes in the hemoglobin and blood cells were caused by the ingestion of methyl-chloride contaminated water on 115 days of a total period of 171 test days. Also, no formates were found in the urine. Autopsy and examination of frozen sections, however, revealed a moderate degree of intracellular fatty degeneration affecting the ascending, descending, and collecting tubules of the kidney. Analysis showed the water to be 75 to 100 per cent saturated with an average methyl-chloride content of 0.595 gm. per 100 c.c. of water. This was the only water given the animals on 6 days of each week of the test.

3. The taste of water saturated with methyl chloride at 68° F. is sharp, sweetish, and sickening when first taken into the mouth, followed almost immediately by a burning sensation. Persons would not drink more than a mouthful or two. It was frequently refused by the animals, even though they were deprived of other water.

—W. P. Yant, H. W. Shoaf, and J. Chornyak (U. S. Bur. of Mines), *Pub. Health Rep.*, 45, 19: 1057–1065 (May 9), 1930.

Titanium Oxide Pigments—The article is principally a description of the technical processes involved in the manufacturing of titanium oxide and the associated bodies, and 15 of its applications in commerce—of chief concern being a pigment to replace lead in paints.

Titanium oxide has now become established as one of the staple pigments of commerce. It possesses a high refractive index and remarkable opacity

and can be produced at a minimum cost while the supply is practically inexhaustible. In a comparison as to whiteness, standard titanium white stands at 390 points, a mixture of titanium white and barium sulphate in the same proportion at 290 points, where white lead stands at 100 points.

Recently, a composite pigment for commercial use has been prepared with a content of 50 per cent titanium oxide. This pigment has a specific gravity which is considerably lower than that of lead, so that a given weight of material spreads over a larger area; at the same time its obliterating power is remarkable. It may be combined with cement and is the only white pigment which combines great opacity with resistance to heat and chemical action. Furthermore, it is not attacked by sulphur dioxide or other sulphur gases, so that it retains its whiteness in the most impure city atmosphere. Finally it is entirely free of any poisonous or harmful properties.

Extensive experiments with rabbits and guinea pigs and even human experiments in ingesting the substance have fully substantiated its harmlessness. It may therefore be combined even in face powders and cosmetics.

In conclusion, the new pigment is not put forward as a substitute for others, it is peculiarly useful as a pigment and has a vast field of usefulness in many industries. Colored pigments may also be easily combined with it.—Noel Heaton, *J. Chem. & Indust.*, 49, 11: 143–150 (Mar. 14), 1930.

Causes of Death by Occupation—The first monograph "Causes of Death by Occupation" appeared some years ago known as *Bulletin No. 207* of the Bureau of Labor Statistics and analyzed the causes of death (among the 2,000,000 then insured) of 94,269 white males 15 years of age and older who died during the 3 years 1911 to 1913. Today

workers 20 years of age may expect to live, on the average, 5 years longer than similar workers could in 1912.

Tuberculosis has always been the predominating scourge of the American workman; but since 1912 tuberculosis of the respiratory system alone has declined over 50 per cent. Only a few conditions, like cancer, have shown a rising death rate.

The present bulletin is based upon experience with 3,250,000 white male policy holders. Of these 112,364 died during the years 1922, 1923, and 1924. As the number of insured persons in each occupation is not known the authors have used the method of proportionate mortality, the utility of which is now granted. The occupations have been classified according to the *Classified Index of Occupations* of the U. S. Bureau of Census. It is noted that after age 25 the mortality rate of the insured group increases above that of males in the registration states, which is considered largely the result of industrial hazards of one kind or another. A contrast is seen between sexes which is thought to be due largely to the absence of industrial hazard in the lives of most women.

The main part of the bulletin is taken up with an analysis of the mortality according to the occupation of some 33 commoner trades and callings followed by a chapter on the principal causes of death among the group considered. Regarding occupational diseases it is said: ". . . and yet a careful study of the experience leaves no doubt that in spite of the special precautions to discover these diseases, by far the larger number of them remain undetected." The great majority of the 321 deaths attributable to occupational diseases were caused by pneumoconiosis (including miners' asthma) and lead poisoning.

A positive association between employment and affliction is more clearly marked in the case of accidental vio-

lence, tuberculosis, the nontuberculous respiratory diseases, alcoholism, and such a strictly occupational disease, for example, as lead poisoning. Typhoid fever is generally prevalent among workers where the water supply is questionable. In regard to cancer, heart disease, and other degenerative diseases, however, the results do not ordinarily reveal a connection with any industrial hazard.

The absence of trustworthy occupational mortality statistics in the United States hinders the work of industrial hygienists, and an investigation such as this one can only partially overcome the lack of reliable data that now exists. It is therefore strongly urged that the U. S. Bureau of the Census compile and tabulate data showing the mortality of workers engaged in different occupations. The reports of the Registrar General of England and Wales give much more complete information on occupational mortality than is available in this country.—Louis I. Dublin and Robert J. Vane, Jr., *Bull., U. S. Dept. of Labor, No. 507*: 1-128 (Feb.), 1930.

An Experimental Study of Abnormalities Produced in the Organism by Electricity—This work was done in the Departments of Neurology and Electrical Engineering, The Johns Hopkins University. Plans for further studies are now in formation. The rat is a convenient animal for studying the effect of electricity upon the central nervous system, since its heart recovers spontaneously from ventricular fibrillation produced by the electric current. Series of animals were studied after application of alternating and continuous circuits of 110, 220, 500, and 1,000 volt potentials. The time that the current was allowed to flow was varied in each group. The electrodes were applied to the top of the skull and to the base of the tail.

The mortality increased in proportion

to the depth of the anesthesia. No sex differences in susceptibility to the current were found. Small, young animals were less resistant than adults. With lower voltages, more injuries were produced with the alternating than with the continuous currents, but with 500-volt potential the effects were equalized while at 1,000-volt potential the continuous current produced the greater injury. Many of the animals that survived the shock showed a paralysis of the posterior portion of the body with the subsequent development of incontinence and hematuria. This paralysis was more common with the alternating than with the continuous current. Some rats died during the first few hours from a hemorrhage in the cerebral ventricles. Many others recovered and appeared normal following the injury. The continuous current often produced symptoms of central nervous system irritation while hemorrhages were particularly common with an alternating current. A large hemorrhage in the spinal cord was found in all the rats in which the posterior portion of the body was paralyzed.

The nerve cells also showed characteristic abnormalities.—O. R. Langworthy and W. B. Kouwenhoven, *J. Indust. Hyg.*, XII, 2: 31–65 (Feb.), 1930.

Proceedings of the Twenty-fifth Anniversary Conference of the National Child Labor Committee held in New York City, December 16–17, 1929—Addresses by some 15 prominent persons are contained in this 94-page bulletin, which is procurable from the National Child Labor Committee, 215 Fourth Ave., New York, N. Y., *Publication No. 361*, Price 50 cents.

Control of the Silicosis Hazard in the Hard Rock Industries—The present paper—part I—deals with a laboratory study of the design of dust control systems for use with pneumatic granite

cutting tools. There is a description of the granite cutting processes, of the tools and machines commonly used, and a classification of the processes according to dustiness, in which it is found that the greatest amount of dust is in connection with hand tools (59.2 million particles per cu. ft.), inside surfacing machines (44.0), outside surfacing machines (43.9), general plant atmosphere (20.2), lathe (17.9), polishing mill (9.0), sandblasting (6.2), saw (4.6), and movements of office employees (1.9).

Laboratory studies were made on dust control methods with a check on numerous features, such as collection of samples, air velocities, variations, air pressure, sharpness of tools, etc., and these in relation to the use of hand tools and surfacing machines.

The efficiency of experimental installations was standardized on the basis of a maximum of 10,000,000 dust particles per cu. ft. of air which was the highest permissible limit set up by Russell and his associates in the U. S. Public Health Service's study at Niagara Falls. It was found that the velocity of air flow at the tool must be at least 200 ft. per minute regardless of the size, shape, and position of the hood and the air flow through it. This value, therefore, may be regarded as a fundamental specification for hood design under laboratory conditions. For the field, it may have to be altered somewhat.

The air flow requirement for the smaller surfacing machine was found to be 315 cu. ft. per minute. A higher rate will be necessary for larger machines.—Theodore Hatch, Philip Drinker, and Sarah P. Choate (Harvard), *J. Indust. Hyg.*, XII, 3: 75–91 (Mar.), 1930.

Occupation and Health—Brochures Nos. 177–183 are included in this assignment of the *Encyclopaedia of Hygiene, Pathology and Social Welfare*,

Studied from the Point of View of Labour, Industry, and Trades. The present Brochure includes special papers upon blood changes due to occupation, clothing or garment trade, cork and linoleum industry, cotton industry, cyanogen and its compounds, cerium, and coal tar. An attached notice states that with this Brochure all trades and hazards coming under the letter "C" are now complete and ready for binding. Similar items under "A" and "B" have been completed since the publication of the Encyclopaedia began in 1925.—International Labour Office, Geneva, 1930. (World Peace Foundation, 40 Mt. Vernon St., Boston, Mass.)

The Comparative Action of 5 and 10 per cent Carbon Dioxide Mixtures as Respiratory Stimulants in Carbon Monoxide Poisoning—Using cats as the experimental animals, observations prompted the two following conclusions: First, that 10 per cent carbon dioxide is more effectual in the treatment of certain degrees of carbon monoxide asphyxia than is the 5 per cent mixture; and second, that artificial respiration should be administered to patients who are breathing but who are suffering from severe grades of asphyxia. In these persons, a brief period of artificial respiration will induce conditions favorable to the stimulation of breathing by the carbon dioxide in the inhalation mixtures.—Douglas P. Murphy and Cecil K. Drinker (Harvard), *J. Indust. Hyg.*, 12, 3: 92–98 (Mar.), 1930.

The Quantitative Measurement of Human Efficiency under Factory Conditions—Conclusions: One may summarize the conclusions to be drawn from the laboratory experiments as follows:

1. The measurement of human efficiency should involve records of both production and energy expenditure. The efficient worker is he who (a) has a high production per unit of energy expenditure, and (b) maintains physiologic equilibrium at this level of exertion.

2. In muscular work the pulse pressure (i.e., difference between systolic and diastolic pressures) and pulse product (the pulse pressure multiplied by the pulse rate) are useful measures of energy expenditure, correlating with oxygen consumption. Supposing that one has allowed for constitutional differences in blood pressure readings of two workers turning out equal production, the more efficient has (a) the lower figure for pulse product and (b) the lower figure for standard deviation in a series of pulse product readings.

3. In mental work and in emotion the pulse product is raised. Variation in pulse product follows changes in attention or emotion more closely than does any other blood pressure or pulse rate factor. Here also the more efficient worker, of two turning out equal production, will have the lower and smoother curve for pulse product. A continued high curve would indicate not so much efficiency of attention as a high degree of strain, and high fluctuations would indicate either lack of ability to fix and sustain attention, or lack of emotional control, or perhaps both.

4. There are normal diurnal variations in blood pressure and pulse rate due, in the working day, chiefly to the taking of food. Correction may be made for these variations, particularly in average curves.

—Osgood S. Lovekin (Harvard), *J. Indust. Hyg.*, 12, 3: 99–119 (Mar.), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

On the Nature and Rôle of the Fatty Acids Essential in Nutrition—This is a supplement to previous work by the same authors (*J. Biol. Chem.*, 82: 345, 1929) in which it was shown that rats on a fat-free diet developed a disease characterized by a scaly condition of the skin later followed by degeneration of the kidneys.

Necrosis of the tail is a symptom and this has been further studied as well as the abnormal kidneys which appear in all autopsies. This degeneration is not the same as that due to vitamin A deficiency, for increased doses of Fraction AD (the non-saponifiable matter of cod liver oil) are without result while vitamin A-free fatty acids are effective. To determine the effect on the kidneys both high and low protein fat-free diets were fed, resulting in evidence of greater kidney destruction in the high protein diet.

An attempt was made to study the water exchange on the fat-free diet. There was found on an average a greater consumption of water, which was reduced by addition of only 10 drops of lard, or 2 per cent of the total diet. Almost twice as much water is consumed as with the controls and this excess is not voided as urine. This loss in the skin and lungs indicates some impairment of these tissues.

To determine the effect of diet on reproduction the fat-free fraction of vitamin E was prepared and given to animals on fat-free diet without noticeable effect toward increased ovulation, which is irregular or absent in the fat-free diet. Doses of curative oils such as corn oil, olive oil or linseed oil immediately restore ovulation. Males on a fat-free diet do not usually mate but when mat-

ing occurs no litters result, while the controls with 10 drops of lard mate and produce normal litters.

An attempt was made to study the curative effect of fatty acids by dividing the diet into groups containing the unsaturated acid such as linoleic, and the saturated acids, stearic, palmitic, etc. Butter and cocoanut oil represent the saturated acids which contain little or no linoleic acid and no other unsaturated acid. Olive oil, corn oil, lard and linseed oil represent the unsaturated fatty acids.

Curative methods of testing were employed after the animals had developed scaly feet and dandruff on the fat-free diets. Butter and cocoanut oil at the 5 drop level are not effective in relieving symptoms. Olive oil is intermediate, corn oil and linseed oil on a par. A study of the composition indicates that linoleic acid is the essential acid and arachidic acid may also be concerned.

Saturated acids were fed as their methyl esters in other experiments together with poppy seed oil, showing that some acid less saturated than oleic is necessary to effect a cure and again pointing to the value of linoleic acid. Lecithin was no more effective than the methyl esters of the fatty acids. This test showed conclusively that the saturated acids in cocoanut oil and methyl stearate will not promote growth or cure the skin regardless of their high food value. Butter, as much as 3 per cent of the total diet, does not cure the skin condition, again supporting the view that vitamin A deficiency is not involved. While cautioning against conclusions concerning human nutrition, it is suggested that warm-blooded animals

cannot synthesize much linoleic acid and that the same is probably true of other unsaturated acids, but that linoleic acid (and possibly others) is an essential fatty acid in nutrition.—George O. Burr and Mildred M. Burr, *J. Biol. Chem.*, 86: 587 (Apr.), 1930.

Effect of Varying Amounts of Menhaden Oil in the Diet on the Composition of the Body Fat of the White Rat. The Storage of Highly Unsaturated Fatty Acids—Reference is made to many investigations showing the importance of fat in the diet and that the body fat of the same species of animals can be much modified. Particularly it was shown in the author's report (*Proc. Soc. Exper. Biol. & Med.*, 24: 704, 1929) that feeding of 20 per cent of whale oil to white rats resulted in an equilibrium between the diet and the stored fat in 4 to 6 weeks. This work covers the effect of varying amounts of menhaden oil on the composition of fat of white rats. The oil used had an iodine number of 169.7, and the fatty acid yielded 54.8 per cent of ether-insoluble bromides. Diets containing from 0 to 30 per cent of this oil resulted in increased amounts of unsaturated acids in the body fat. Adult rats were used and were partially starved for 4 weeks by a fat-free diet to which was added a small amount of cod liver oil (4 c.c. per kg. dry mixture).

Tables show the amount of oil administered, food and oil consumption, and the weight changes. Physical conditions at the end of the experiment were good and no deleterious effects observed with 30 per cent menhaden oil.

Five rats from each group were killed and body fat rendered and analyzed. The iodine number was determined and the fat brominated. The analyses show unmistakably high deposit of highly unsaturated fatty acids fairly proportionate to the amounts administered in the menhaden oil.

The amounts of unsaturated acids deposited vary from 9.7 to 17.2 per cent and, with the 5 per cent diet, to 30 per cent menhaden oil. Since the deposited acids are more unsaturated than those of the original menhaden oil the explanation is offered that either in the metabolism of certain acids of the fish oil those of lower weight are removed and those of higher weight, that is, more unsaturated acids, are deposited, or that the unsaturated acids are further desaturated in the body by the introduction of more double bonds.—J. B. Brown and S. G. Morris, *J. Nutrition*, 2: 509 (May), 1930.

Studies of Vitamin C in Fresh and Canned Tomatoes—In view of the importance of tomatoes as an antiscorbutic, experiments were undertaken to determine the relative value of canned tomatoes to fresh, and to answer other questions involved. The curative method was employed on guinea pigs which had been fed scorbutic diet until symptoms such as "jerky run" or swollen wrists were noted. Feeding was continued 16 days, followed by autopsy.

The ration was chiefly soya bean flour, dried yeast, casein with mineral salts and butter fat. Two types of canned tomatoes, cold-pack and open kettle, were used, sterilization consisting of boiling 20 minutes in water. Green tomato pickles were prepared without spice, onion and pepper. Artificially colored tomatoes were produced by treatment with ethylene air 1 to 1,000 from 4 to 8 days.

Results show 2 gm. daily of raw tomatoes, field ripened, insufficient for recovery, which is practically complete with 3-gm. dosage. Practically complete recovery was found in the cold-pack canned tomatoes with 3-gm. dosage after these cans had been stored 9 months. Tomatoes canned by the open kettle method did not give complete re-

covery with even 4-gm. dosage, indicating loss of vitamin C by oxidation. In cold-pack, field ripened tomatoes stored 15 to 20 months, a 4-gm. daily dose was necessary. Storage loss is also shown in the green canned cold-pack tomatoes which required 5-gm. dosage after 9 months, and after 15 to 20 months this amount did not result in the same degree of recovery.

By comparison, greenhouse ripened tomatoes are not quite so potent in vitamin C as those ripened in the field. The ethylene colored tomatoes required 4 gm. for recovery, indicating that ethylene does not prevent the development of vitamin C but is comparable to the greenhouse ripened tomatoes. Green tomatoes ripened in a dark room effected practical recovery with 3-gm. dosage, showing the development of vitamin C after severing from the vine. Field matured green tomatoes were stored until soft, then fed at the 5-gm. level, which showed approximate recovery, indicating a superiority over the fresh canned tomatoes from the vine but comparable with these same tomatoes canned by the cold-pack method, indicating a slight superiority for this method as a source of vitamin C compared to the raw, green tomatoes.

The vitamin C content of green tomato pickles was found to be negligible.—Bertha Clow and Abby L. Marlatt, *J. Agri. Res.*, 40: 767 (Apr. 15), 1930.

Further Evidence for a Third Accessory "B" Factor—This author has previously presented evidence of the division of the vitamin B Complex into three components (*Biochem. J.*, 23: 689, 1929). This paper records further evidence with respect to these factors. Similar basal diets as on a previous experiment were employed and 3-pigeon-day-doses (approx. 1.0 mg.) were given each rat daily. Vitamin B₂ was obtained from the filtrate of the preparation of vitamin B₁ and was found active

only in the mercuric sulphate precipitate. Details of this separation are to be published.

Two types of experiments were conducted, first, rats which were brought to constant weight on the basal diet plus vitamin B₂ ceased growth at the end of 2–3 weeks. Temporary response followed the addition of vitamin B₁ but no further response by further addition of B₁ or B₂ or both. Vitamin B₃ preparation was administered daily by mouth, and graphs indicate definite resumption of growth by the supply of B₃.

In the second experiment, rats were brought to constant weight without addition of any of the B vitamins. Vitamin B₁ and vitamin B₃ in amounts shown adequate in previous experiments were fed without increased growth even when doubled. Growth was immediately restored by the unit quantity of vitamin B₂. The suggestion is offered that the vitamin B₃ factor forms an insoluble mercury salt with mercuric sulphate. The growth curve also indicates that the storage period for vitamin B₃ is approximately 5 weeks compared to 3 weeks with vitamin B₂.—Vera Reader, *Biochem. J.*, 24: 77, 1930.

Heat Resistance of the Spores of Clostridium Botulinum—The purpose of the work reported in this article was to supply spores in large quantities for heat resistance studies. In the course of the work 10 different lots of peptic-digest medium, 12 gelatin mediums, 12 mediums in which peptone served as the basic nitrogen constituent, 4 meat mediums, and over 100 different batches of casein-digest medium with many variations, including the addition of salts and vegetable extracts, were employed for the production of spores of representative strains of *Cl. botulinum*.

Spores grown in 4 per cent peptone showed a resistance of from 1½ to 2½ hours. The addition of phosphate raised the heat tolerance to 4 hours; the

effect, however, was not constant. The addition of glucose and the increase in concentration of peptone raised the number of organisms but not the resistance. A standard casein-digest medium supplemented with Liebig's meat extract was selected as most favorable for the routine production of *Cl. botulinum* spores.

Different lots of casein medium prepared under similar conditions varied in their ability to produce heat resistant organisms. The same lot of medium consistently yielded identical results. Supplementing with different electrolytes, sand, glucose, olive oil, protein or vegetable extracts did not improve the basic substrate. Attempts to increase resistance by selection failed.

Incubation temperatures of 28°, 37° and 41° C. showed little influence on the heat resistance of the organism.

The most resistant organisms were found in 4- to 8-day cultures. The degree of anaerobiosis had no evident effect on the heat resistance of the spores. The apparent heat resistance of a spore suspension increased with its density up to approximately 1 billion per c.c.; beyond this limit it was considered constant.

Spores preserved in their own liquor in the icebox and in a dry state usually deteriorate on standing. Numerous products, however, remained constant over periods of 4 months. As a result of 46 resistance experiments on small spore samples, an average heat tolerance of 4 to 4½ hours was shown.

When the results from 44 pools prepared by the Sharples centrifuge are considered, two maximums, at 3½ and 5 hours, are evident.—E. W. Sommer, *J. Infect. Dis.*, 46: 85 (Feb.), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

The Public Health Nurse and Communicable Disease—Any public health nurse can tell you that some of the families most needy of good nursing care are often those in which one or more children are ill with a communicable disease. Usually the mother has to give nursing care in addition to her other heavy duties, if she has a large family, and this is so much more difficult if the house is small and there must be isolation of the patient and careful technic in guarding the rest of the family and herself. This is one time when the public health nurse is needed badly; yet many visiting nurses in the smaller

communities are not allowed to give bedside care in these cases for fear the public will feel that they will carry the disease from house to house, though no case has ever been reported in which a visiting nurse has carried an infection.

Again school nurses many times visit the homes of school children ill with a communicable disease. One nurse not long ago visited a school child ill with measles. The mother escorted her into the darkened room (which the National Society for the Prevention of Blindness says should not be darkened) and sat in a chair by the sick boy, holding her six months' old baby in her lap. She was eager to take all the nurse's suggestions about the nursing care of her son, and was much surprised that

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

she should not take her baby into the sick room.

It would be ideal if school nurses, board of health nurses or visiting nurses could visit every home in which there is a case of communicable disease and after demonstrating nursing care to the mother leave one of the pamphlets explaining the care and hazards of that particular disease. These pamphlets are attractively written and furnished by some of the life insurance companies, or state health departments. Some few mothers may not read them, but more will—and pass them on to the neighbors. An alert nurse will say, "Be sure and have your husband read it, too."

It would be a God-send to any public health nurse if she could also leave a pamphlet with the mother such as has just been published by the Iowa State Board of Health, *Management of Cases of Communicable Diseases in Isolation or Quarantine at Home or in Hospital*, written by the Directors of the Division of Preventable Diseases and the Division of Public Health Nursing. Most of the pamphlet "deals with the arrangement of the patient's room, the precautions to be taken to prevent the spread of disease, and the method of disinfection to be used during the course of the illness and after recovery." It is written very plainly and attractively with plenty of illustrations; any mother can understand it.

The physicians and health officers complain that so many families go to great length to escape or avoid quarantine. It is probably because most of them do not really understand the need of it. This same pamphlet "contains certain definitions and citations of the laws and regulations pertaining to notification and the placing of a warning sign on the premises."

Surely the nurse who has visited a case of communicable disease, has helped to interpret the doctor's orders in regard to it, has demonstrated nursing care and

left a pamphlet like this one from Iowa, together with a specific pamphlet about the disease, has done a great deal to protect the patient and his family and the community, and to make it easier for the physician and health officer.

Public Health Nurses in Michigan, 1929-1930—

Number of county nurses (exclusive of Children's Fund)	56
School nurses	163
Tuberculosis nurses	28
Industrial nurses	58
Visiting nurses	62
General Public Health nurses	89
Children's Fund of Michigan nurses	14
Metropolitan Life Insurance Co. nurses ..	23
State Department of Health nurses	9
<hr/> Total	<hr/> 502
Number of counties employing nurses ...	31
Financed entirely by Boards of Supervisors	19
Financed by Red Cross and supervisors ..	6
Financed by tuberculosis funds	9
Counties having nurses from the Children's Fund of Michigan	9
Number of County Health Units financed by Children's Fund	9
County Health Units financed by Supervisors, Rockefeller Foundation and State	5

The nurses with the Children's Fund of Michigan are all doing county work and the majority of the tuberculosis nurses have a county wide program.

The above figures do not include the staffs in Detroit.—*News Letter to Public Health Nurses*, Bureau of Child Hygiene and Public Health Nursing, Mich. Dept. Health, May, 1930, p. 5.

The Staff Education Plan in Montreal—Weekly conferences are held in each district in the Montreal District of the Victorian Order of Nurses. Plans are made ahead of time to have members of the staff take a definite part, in order that the conferences may not become dominated by the supervisor.

Last winter the nurses prepared a series of ante-natal talks for mothers to

be given at the district conferences. They chose their own topics and prepared 4 papers with some help from the supervisor. This gave them much needed practice in planning group talks.

We quote *The Canadian Nurse* of February, 1930, as to why the plan is of value:

1. To the Staff Nurse:
 - (a) Because it provides her with the incentive to do considerable reading;
 - (b) The opportunity to do some creative work;
 - (c) The opportunity to do some public speaking.
2. To the Supervisor:
 - (a) It enables her to evaluate the teaching ability of the nurse;
 - (b) To select nurses best suited to answer the call for "health talks";
 - (c) The opportunity of knowing, and consequently being the better able to strengthen, the weak joints in her armour.
3. The whole group is benefitted by the discussion which follows and the new nurses on the staff are helped and stimulated.

To make reference reading easier a committee, appointed each month from the staff, looks through the magazines and tabulates and files all articles that they consider will be of value to them in their work.

No extra time is allowed for any of this work. If possible, some of it may be done in office time, and the stenographer does what she can to help. The benefits that accrue to the nurse should more than offset the disadvantages, and most of the nurses are willing to admit that the time is well spent.—Staff Education in the Victorian Order of Nurses, Canada, *Internat. Nurs. Rev.*, Mar., 1930, p. 206.

We Need a Higher Standard of Admission to Nursing Schools—Of the 524 nursing schools situated in the northeastern states comprising New England and the Middle States 56 per cent require only 1 year of high school for entrance, 28 per cent require 2

years, 2 per cent require 3 years and 14 per cent have a 4-year requirement.

"One of the three great questions involved in the training of nurses or any other group of professional workers is the question of their preliminary education." Twenty-nine out of each 100 students in these 524 nursing schools had not enough preliminary education to enter any normal school in these 10 states. However, 68 per cent of the total students accepted in the schools had had 4 years of high school education, though this standard was not required in the states in which they were located.

Nursing leaders agree that 4 years of high school should be one of the standards of admission to a nursing school, for as Dr. Burgess says in *Nurses, Patients, and Pocketbooks*, "The young women who in this day of free education have not had the ambition, energy or good sense to carry them through high school, are not the material at all which we should expect to make nurses."

Maryland, Oregon, Rhode Island, Utah and Washington require 4 years of high school for admission to their nursing schools, and Colorado, Alabama, New York and Idaho have recently passed laws requiring high school education for admission; all other states require less.

An intelligent public opinion must be produced on the facts in training schools as they are operated today, and nurses must lead in the reforms that must take place in the nursing profession; but it is futile to expect that any discussion of nursing school needs will have any effect upon the situation unless it "overflows the banks of your professional stream and engulfs the general public."—E. Everett Cartwright, This and That in Nursing Education and Practice, *Am. J. Nurs.*, XXX, 5: 617, 618, 619, 624, 627 (May), 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

A Neighborhood Demonstration
—A Clean-up Demonstration was conducted by the various community and social agencies connected with the Lower East Side Community Council in New York City. They chose a small area of two square blocks—from Jefferson to Rutgers Streets and from Madison to Cherry Streets—so that the checking up would not be impossible.

The drive started off with all sorts of meetings—interested agencies, the landlords, fathers and mothers, and children, and the Madison House Clubs, etc., all eager for action.

People were very much interested, fathers being particularly responsive and anxious to help in inspection, for which purpose they received letters as credentials. The children were held responsible for cleaning houses and had daily reports to make on printed forms. They were given a point system for grading the homes they described. The schools held an essay contest in which all the classes from 4B to 9B participated, each class getting a button, and a medal being given to the best essay in each grade—all this at a formal assembly.

One hundred and fifty organizations sent out trained visitors with sets of printed instructions so that each family in the 1,356 apartments of the district was visited.

The landlords agreed to help, improving hallways, shaftways, etc., feeling, too, that it would help them to keep their houses filled.

The educational side of the demon-

stration included the distribution of informational pamphlets, display posters, movies, lectures, lantern slides, essay contest, and score cards, badges, etc., programs at church and Hebrew schools, newspaper publicity, and a printed report of the demonstration. The League of Women Voters issued a pamphlet on violations of the law involved.—Babette Langsdorf.

Welcome to a Guest Editor—Welcome to Dr. H. E. Kleinschmidt, health education director of the National Tuberculosis Association, who will edit this department in the September and October issues.

The year round editor plans to sail eastward July 16, reaching New York again September 19. The main objectives are the International Hygiene Exposition at Dresden and the social museums in Munich, affording unequalled opportunities for the study of German methods of graphic presentation of facts and ideas.

Dr. Kleinschmidt, who has kindly agreed to carry this department, has had a more varied experience in health education, probably, than anyone else. In two national and one city health agencies, and a state department, he has produced motion pictures, exhibits, posters and other materials; has talked and written on the subject; and has been a pillar of the popular Health Education Section of the A. P. H. A.

No instructions have been passed on to Dr. Kleinschmidt. We count on a different treatment of the subject in those two issues. Much, of course, depends upon what is sent by health workers to his address, 370 7th Ave., New

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

York, N. Y. He will welcome questions and problems, and those good samples of your publicity materials and descriptions of devices and methods.

Early Diagnosis Campaign, 1930
—The campaign succeeded this year in reaching very effectively the medical profession through the distribution of the diagnostic manual, "Childhood Type of Tuberculosis." Though the book was an expensive printing job, it was necessary to print 40,000 copies to meet the demand. Free copies were made available to the 4,500 senior medical students. Comments from medical teachers, specialists, and practitioners were numerous and universally favorable.

Dr. Algernon B. Jackson, professor of hygiene of Howard University, Washington, D. C., was engaged to make a special lecture tour to 12 Negro normal schools and colleges in the South.

For Negro groups, there was a Negro poster like that for general groups except that it was illustrated with a portrait of a Negro child. This poster was popular greatly beyond expectations, and for no other reason, we believe, than that it featured the Negro child. In many places, tie-ups were made with Negro Health Week.

Radio announcers and advertisers were furnished with announcements and short talks. A considerable number made use of them. One station asked for additional copy because the previous copy had proved so popular. We found also that, while it was difficult to secure good hours on the larger stations, our local secretaries succeeded in getting liberal allotments of time on local stations. One state association arranged for a series of ten 5-minute talks on successive days by different speakers.

The 6,000 24-sheet billboard posters were favorably received, but for the first time in our experience protests against the use of the billboard in general were

heard from various parts of the country. A number of persons and organizations deplored the fact that tuberculosis associations encouraged the perpetuation of the billboard by using them. The National Association has not yet taken a stand on the question nor adopted a definite policy.—H. E. Kleinschmidt.

Health Education in a Professional Magazine—In *Public Health Nurse*, 370 7th Ave., New York, N. Y., June, 1930. 35 cents. "The Nurse's Message of Child Health to the Family" (includes interpretation of printed publicity); "Child Study Program Applied to a Public Health Organization" (includes child study and health discussion groups); "The Nursery School—A Learning-Living Place" (includes "learning through living"); "New York Experiments in State-wide Staff Education" (Division of Health Nursing, State Department of Health); "Community Organization for Health" (includes the education of women in England); "Responsibilities and Duties of Advisory Board Members" (includes plea by a board member for more education of board members); "Report of the New England Health Institute"; "One Day Institute Board and Committee Members' Section, Rhode Island"; "Board Members' Institute, Syracuse"; and "A Year-Round Publicity Program for Public Health Nursing Organizations."

Why Not the Silent Film?—"Ill blows the wind that profits nobody."—Shakespeare.

The advent of the Talkie has opened new and heretofore unavailable opportunities to the tuberculosis and public health movement in that the silent film field has been abandoned by the commercial groups and is now available for complete and non-competed exploitation by the educational bodies.

Whereas Hollywood previously

crowded the non-entertainment film out of the picture and allowed it only a small margin of usefulness, now, since the movie has found its voice, we are free to utilize the commercially abandoned old-style cinema. If we now appreciate our opportunities and hasten to embrace them, we will add a valuable instrument to our educational means.

The recent and phenomenal development of the amateur movie, the perfection of the amateur movie camera capable, because of its rapid lenses, of taking pictures in ordinary light, the production of simple lighting facilities which can be attached to practically any lighting circuit, the availableness and cheapness of the 16 millimeter reversible film purchasable at less than \$5 per 100 feet, including all processing, and the perfection of the amateur projection machine, and screens which give good pictures make the exploitation of the silent film easier and cheaper now than before.

The spheres of exploitation of the silent film still remain wide. The public school assembly, the classroom, the mothers' meeting, the boys' and girls' club, church groups, the union meeting, all of these and many others offer opportunities for the showing of silent films.

Amateur equipment is relatively inexpensive, easy to handle and easy to transport. The camera need not cost more than \$100—the film would cost less than \$5 per 100 feet, \$20 for 400-foot reels, equal to 1,000 feet of standard 36 millimeter film. (Projection time approximately 16 minutes.)

Projection machines cost from \$50 to \$250. Sixteen millimeter films are of the safety type—that is, non-inflammable. The films are easy to handle and to store. Neither license nor booth is required for projection. Excellent screens of the glass bead variety are available to receive the projected picture. These also are easily transported. Several lecturers employed by the Col-

gate-Palmolive Organization have for several years made the circuits of the schools delivering lectures on oral hygiene and have carried without difficulty their projection machines and films.

The amateur films offer new opportunities which the professional films did not. Thus, since nearly every city has a film service where the 16 millimeter films may be rented, these services can be exploited for the distribution of health films. "Jinx," "The Kid Comes Through," and a number of others of our health films can be converted into the 16 millimeter size and loaned for projection at private homes.

Schools could be persuaded to make their own health films on a project method: the English, biology and hygiene departments could supply the plot, the dramatic director choosing and directing the cast, the manual training department supplying sets, etc., and the whole school coöperating in finishing the project.

The costs of the project could be recovered through admissions charged at the showing of the film. The interest of the parents could be enlisted in the review of the film.

There are a variety of ways in which this last opportunity could be exploited. Pantomime and puppets could be used in the making of health films. Prize competitions might be held among the schools for the best film produced. Health organizations could coöperate with schools by making available, on a loan basis to the schools requiring them, motion picture cameras, lighting facilities and projection machines.

Visual instructions in health could thus be promoted and recognized by all. There are items which can best be presented by the silent film. The health movement never adequately exploited the opportunities represented by the motion picture but now a new opportunity is offered to us.—Iago Galdston, M.D. (Mimeographed copies of above

free from National Tuberculosis Association, 370 7th Ave., New York, N. Y.)

Dr. Galdston says so well and in such specific detail what we have hinted at in this department. We believe that health and social welfare agencies have had thrust upon them practically a new medium and a new method. The growth of the amateur movie club seems to point the way. We look forward to local, state, and national health and social welfare movie competitions. Later there will be discussion in this department of the use of amateur movies.

The best single source of information is the Amateur Cinema League (and its magazine, *Movie Makers*), 105 West 40th St., New York, N. Y.

A second source is the *Educational Screen*, 5 South Wabash Ave., Chicago, Ill., with an amateur movie department edited by Dwight R. Furness, who is active in the Social Work Publicity Council. Write to both above addresses for sample copies.

Publicity Task of Mental Hygiene
—From Germany Dr. Hans Roemer brought to the International Congress for Mental Hygiene a description of the opposition to up-to-date treatment of the mentally diseased which might apply very well to other countries. To public opinion, he says, the mentally diseased individual is unpleasant, undesired, inconvenient. He is looked upon as burdensome, annoying, even sinister.

Prejudice is directed not only against the insane but against the asylum and the alienist. These prejudices of public opinion that, largely in the form of antiquated laws, have been carried over from obsolete stages of development to our own time have become great hindrances to progress in care of the insane.

On the other hand there are some rays of light that promise a better future. In the important field of the administration of social service and of law, the psychiatrically oriented system

of an active social pedagogy has begun to regulate the relations of the conspicuous psychopath to society. This new social, educational orientation will, through public opinion, gradually prepare the way for improvement in the treatment of the insane.

We alienists, Dr. Roemer continues, see clearly laid out for us the road to progress. We have to win for the care of our patients a place in the realm of active social pedagogy within the field of health service, and to win over public opinion by means of systematic enlightenment.

The removal of the hindering prejudices that public opinion has dragged along from past days can be accomplished by psychiatric enlightenment in connection with the general education of the people in hygiene.

In the solving of all these problems we must assure ourselves of the coöperation of the members of private social service organizations who have already so successfully won the far reaching help of public opinion in other common goals.
—Dr. Hans Roemer, *To What Extent Does Public Opinion Help, and to What Extent Does It Impair the Work of Mental Hygiene?* First International Congress on Mental Hygiene.

MAGAZINE ARTICLES

"Cinderella's Slippers," by G. F. Alsop, M.D. *Woman's Journal*, 171 Madison Ave., New York, N. Y. June, 1930. 25 cents. Feet, shoes, health.

"Fat or Thin Women," by Brenda Ueland. *Saturday Evening Post*. May 10, 1930.

"Right from the Heart," by R. E. Wadsworth, M.D. *Collier's*. May 24, 1930.

"Sensible Sixties," by S. G. Blythe. *Saturday Evening Post*. May 17, 1930.

"The World's Future Population," by R. E. Kuczynski. *New Republic*, 421 West 21st St., New York, N. Y. May 7, 1930. 15 cents.

BOOKS AND REPORTS

The Story of San Michele—By Axel Munthe. *New York: Dutton, 1929.* 530 pp. Price, \$3.75.

This autobiography is entirely different from any which the reviewer has ever read. It is the story of a Swedish physician who graduated in Paris and acquired a large practice, becoming a fashionable physician. He always found time, however, to look after the poor in an Italian as well as a Swedish colony. His outstanding characteristics seem to have been a clear insight into human nature, an intense love for animals of all kinds, especially dogs, and a revolt against the social injustices. The book is not so much a detailed description of his life as a succession of dramatic incidents. His description of the cholera epidemic in Naples is ghastly, as is his account of the diphtheria and scarlet fever outbreaks among the poor Italians and Swedes in Paris.

The book is beautifully written. The author has a fine dramatic instinct. His description of death, which he personifies, as he has seen Him in the wards of the hospital, on the battlefield, and elsewhere, is most dramatic. He was a student of Charcot's, and apparently one of that great man's favorites, though he offended him later. He attributes his success largely to the influence of his teacher. He found, as do most physicians who handle nervous diseases, that many of his patients were suffering from imaginary diseases, and it is quite amusing to read how he substituted "colitis"—whatever that term meant—for appendicitis, which was then the fashionable ailment, and how he cured these cases by getting his patients—usually rich and idle women—interested in

something outside of themselves—a dog in one case, making dolls for poor children in another, etc.

Apart from the intense interest of the story itself, the book will recall to all physicians, particularly those specializing in nervous affections, incidents in their own lives. Eventually the author broke down under the strain, bought the retreat known as "San Michele," from which the title is derived, where he established himself, founded a retreat for the animals and birds he loved so well, and reconstructed some of the relics of Roman civilization which abounded in the ruins. After a rest he recovered, and for some years practised in Rome during the fashionable season, becoming the fashionable doctor of that city as he had been in Paris. We understand that the proceeds from the book will be given to the Society of Naples for the Protection of Animals.

It is hard to praise this book too highly. The introductory chapter is difficult, but from that time on, one's interest is held without a break.

M. P. RAVENEL

The Diagnosis of Health—By William R. P. Emerson, M.D. *Appleton, 1930.* 272 pp. Price, \$3.00.

The most refreshing points of Dr. Emerson's new book are found in the definite start and goal he sets up for the individual who reads that book with a view to bettering his own health. Add to those points the fact that the writer simply and convincingly sets forth how to proceed from that start to that goal. One can understand the satisfaction any individual floundering about in search of health may get from this volume.

In his Part I, Dr. Emerson immedi-

ately puts the emphasis where it belongs—in a book carrying this title—on health; not on disease cure, treatment, or prevention. The various chapters of this part interpret health rating, signs and essentials of health, understanding and use of the weight table, the individual's history approached from the health angle rather than the disease angle, health intelligence as a factor in health building—all developed with a vision reaching far beyond the diagnosis toward the follow-up, leading in the direction of health—positive.

Part II, Training for Physical Fitness, very logically presents the analysis of certain procedure and results as observed in actual class study and experiment in nutrition, in work, in rest, in recreation, and in health habits in their relation to individual health. As Dr. Emerson says, "The whole object of the class is to help the student help himself." The reader is quite likely to feel, also, that the object of those chapters is to help the individual help himself, wherever he is.

Part III, Problems in Health Diagnosis, covers certain conditions found to exist in groups and with individuals, and how those conditions have been handled or are waiting to be handled to the increased health of the individual.

In addition to the clarity with which these three divisions of Dr. Emerson's book point to the road the individual should travel toward his own health, *Diagnosis of Health* also gives pointed evidence that all such increase in individual health necessarily makes for an increase in all public health and general public welfare. LENNA L. MEANES

What Is Eugenics?—By Major Leonard Darwin. New York: Galton, 1929. Price, \$1.00.

This little volume is practically a condensation of the larger book published in 1926 by the same author, *The Need for Eugenic Reform*. Major Darwin is

the greatest authority on the subject of which he treats in the world today, and what he writes is worthy of close attention.

The book can be commended for general reading, professional as well as lay.

M. P. RAVENEL

Shattering Health Superstitions—

By Morris Fishbein, M.D. New York: Horace Liveright, Inc., 1930.

245 pp. Price, \$2.00.

The number of superstitions discussed in this book exactly equal the variety of pickles of a certain brand. Of the fifty-seven superstitions all but two are demolished. These two which survive on some basis of fact are—that brainy people have big heads; and that rheumatic joints, like the weather bureau, are sometimes reliable in forecasting changes in the weather. The book has fifty-seven chapters—one superstition per chapter.

Dr. Fishbein takes us on a tour of the darker recesses of the human mind which lie off the paths of everyday expression. Apparently there are still bats in many human belfries.

There is some evidence of hasty preparation, which is not to be wondered at considering the enormous weekly output of this very prolific writer.

In discussing smallpox on page 202 he says, "Essentially, vaccination is the means of giving the person a mild attack of the disorder." According to Rosenau, smallpox may be converted into cowpox by passing variolous matter through calves, but when thus established it remains fixed and never reverts to smallpox. Since modern vaccination requires the use of bovine virus, the author's definition might better apply to the Chinese method of insufflation of human virus into the nasal cavity. The hope there is to give the person a mild attack of the disorder.

In discussing the transmission of disease causing organisms by the air route,

the wisdom of excluding the following statement may be questioned: "Nowadays it is generally recognized that few diseases are spread in this way, and there is even beginning to be some doubt that moist droplets expelled from the nose and throat will carry with them the germs of disease sufficient in number to affect other persons." Fortunately, the author adds, "In the interest of safety against tuberculosis, pneumonia and other diseases affecting the lungs particularly it is best for people to continue to cover up each cough and sneeze."

W. W. PETER

The Immunology of Parasitic Infections—By *William H. Taliaferro, Ph.D.* New York: Century, 1929. 414 pp. Price, \$6.00.

This book fills a distinct need in the fields of immunology and parasitology, for hitherto there has been no collection of immunological contributions in parasitology, to say nothing of an interpretation of many of the findings. The purpose of the book is best stated in the words of the author in his preface:

Besides stimulating interest in this field I hope that the present work will hasten the incorporation of these experimental data into both parasitology and immunology where . . . it has been largely neglected. By achieving this the parasitologist will undoubtedly gain new concepts . . . and the immunologist can obtain unique material for certain immunological questions.

The author further points out that the zoölogist's concept of zoöparasitism differs in its viewpoint and in its use of certain terms from the concept of bacterial parasitism held by bacteriologists and workers in medical fields by whom most of the work in immunology has been done.

The arrangement of the material makes it especially available to readers interested in special fields of investigation. After an introductory chapter dealing with parasitic infections in general and a chapter describing the various phenomena used in studies of im-

munity, various parasitic diseases are considered in detail from the standpoint of the immunological responses they provoke in the host. Of particular interest are the chapters on the protective and curative actions of immune serums and hypersensitiveness and cutaneous tests used for diagnosis. Much misunderstanding has existed regarding the protective and curative action of immune serums because of the conflicting nature of the reports. By collecting them all and criticising them from the point of view of the parasitologist, Dr. Taliaferro has made a contribution of considerable value. The bibliography requires more than passing mention, for it is unusually complete and the references have been given in detail in such a manner as to make them most useful to the student and investigator. Likewise, the index has been carefully done and is exceptionally complete.

N. W. LARKUM

Factors in the Sex Life of Twenty-Two Hundred Women—By *Katharine Bement Davis, Ph.D.* New York: Harper, 1929. 430 pp. Price, \$3.50.

The value of this book cannot be overestimated as regards a new fund of knowledge, and the possibility of the application of that knowledge in the field of social hygiene. It is enlightening in so far as it gives a better insight into the sex life and sex motives of at least one group or a representative number of such a group of women. It is interesting coming at this time when the trend in modern literature, the stage and the screen is toward the discussion of more and more intimate sex relationship.

To say that its fund of information is exhaustive would be overestimating the book and underestimating the complexity of the sex in question. A group of 2,200 women, most of them college graduates and nearly half of them en-

gaged at one time or another in teaching, does not represent a cross-section of American womanhood. However, the histories supplied by these women do give a definite understanding and a definite knowledge concerning the sex life within their own social and educational spheres. As the author herself states, the statistics set forth by this group will hardly hold for a similar representation of women from other walks of life.

One of the results of greatest importance in this investigation, to my way of thinking, is the proof of at least reasonable success in using the questionnaire method of compiling statistics. To be sure, religious training, social environments, education, and many other factors play a part in the correctness of answers to such inquiry. Subconscious, as well as conscious inhibitions modify their exactness. On the whole, however, it would seem that information was honestly given and I truly think that the success of this work opens the way for vast fields of investigation through the avenue of the anonymous questionnaire method.

LOUIS E. SCHMIDT

Sewerage and Sewage Disposal. A Textbook—By *Leonard Metcalf and Harrison P. Eddy*. (2d ed.) New York: McGraw-Hill, 1930. 783 pp. Price, \$6.00.

The second edition contains much new material, bringing the subject matter quite up to date. It comprises 783 pages, an increase of 185 over the first edition, 343 of which are devoted to sewerage and 400 to sewage and sewage disposal. The whole has been rearranged and in large part rewritten. In the first chapter will be found a brief but excellent historical review of the entire subject with an outline of the principles involved, including those of plumbing.

The problem of runoff is dealt with in Chapter III with more thoroughness

than the writer has seen in other textbooks, explaining the application and importance of recognizing the "zone principle" in estimating storm flow by the rational method—a matter frequently ignored by the practicing engineer.

If carried out in detail the computation is somewhat laborious and the authors point out that the curves shown in Figure 22, based on a rectangular area with a length equaling four times the breadth, will give reasonably satisfactory results with ordinary collecting areas, while, for preliminary estimates without adequate rainfall data, the McMath formula, judiciously applied, serves an excellent purpose.

Much fresh material will be found in the chapter on the Hydraulics of Sewers, such as "banking" on curves, non-uniform flow near outlets having a free discharge, backwater, the hydraulic jump, the Venturi flume and chemical methods of gaging—subjects not always found in textbooks on sewerage.

Particular mention should be made of the treatment of side weirs and pumps (Chapter VI), loads on sewers (Chapter IX) and the chemistry of sewage (including a discussion of hydrogen ion concentration).

Dilution is adequately treated in Chapter XII, taking advantage of the excellent experimental work recently carried out by the U. S. Public Health Service on the Ohio and Illinois Rivers. The still more recent results of experiments in dilution and the dispersion of sewage discharged from submerged outlets at Los Angeles and other California cities were unfortunately not available at the time of publication.

In speaking of screens (Chapter XV), the authors say: "The term *screen* should be limited to the type employing wire cloth or perforated plates." What are commonly called *bar screens*, such as those installed at Hamburg, Frankfurt, and London, are classed as *racks*.

If these have a clear opening over 2" in size they are designated as *coarse*; with spaces of 1" to 2" as *medium*, and if less than 1" as *fine*. Screens with openings $\frac{1}{4}$ " or more in size are *medium* and those of smaller size *fine*. Regarding efficiency tests for screens, the authors state (p. 503):

Whether it is practicable to ascertain, even with approximate accuracy, the screen efficiency by determining the suspended or settling solids in the sewage before and after screening is doubtful, for a very large proportion of the substance removed, especially with coarse screens, is of such a nature that it cannot be sampled fairly by practicable methods.

Skimming tanks, which are a rather recent innovation in sewage works, are also described in Chapter XVI (pp. 513-516).

Why the term "Sedimentation Basin" is used in the caption to Chapter XVI instead of "Sedimentation Tanks," as in the following text and as commonly used in practice, is not clear.

Referring to the activated sludge process (Chapter XVIII), a distinction is made between Diffused-air Aeration and Mechanical Aeration by denoting the latter as Bio-aeration, confining the use of Activated Sludge to the former. Air cleaning and contact aerators are given the prominence they deserve in dealing with the subject of activated sludge.

The final chapter (XXI) on Financial Considerations will be found valuable to the inexperienced engineer planning the installation of sewerage works. The methods of estimating, the significance of index numbers, overhead expense, contractor's profit, engineering costs and interest during construction, in addition to unit prices, are explained and given due weight.

At the end of each chapter references to original sources of information are given and, where desirable, practical examples are worked out as a guide to the method to be followed.

The book contains a fund of information brought up to date in a clear, con-

cise style. Having received the scrutiny of Professors Richard G. Tyler and Gordon M. Fair as well as other competent authorities before presentation to the public it will serve as a safe guide to the practicing engineer as well as the student, for whom it is especially intended.

The general make-up of the book is excellent, the illustrations are numerous, well-selected and clear, and there is an index of 38 pages. It will serve as a convenient book of reference and a worthy successor to the many treatises on sewerage that have appeared since those of Latham and Adams.

KENNETH ALLEN

Through the States with a Seeing Eye—By *Richard J. A. Berry, M.D., F.R.C.S., F.R.S. (Edin.)*. Bristol: *John Wright and Sons, Ltd.*, 1930. 200 pp. Price, \$1.75.

This delightfully written little book is an account of a trip through Canada and the United States made by the author as the guest of the Rockefeller Foundation. Professor Berry certainly has a "seeing eye," and what we are unaccustomed to expect from an Englishman—a keen sense of humor. He shows more knowledge of the history of the United States than many of the natives possess. He cannot help poking a little good natured fun at us over having so many largest cities in the world, so many most beautiful streets in the world, etc. One cannot but regret that he did not include some comments on the various medical schools he visited.

The 25 chapters were broadcast over Australia in an attempt to create friendship for "The States." His comments on prohibition are particularly sane and to the point.

Altogether, the book can be unreservedly recommended. It does everyone good to get the other fellow's point of view of himself once in a while.

M. P. RAVENEL

Values and Methods in Health Education—By *Walter Frank Cobb, M.D. Evanston, Ill.: Row, Peterson & Co., 1929. 362 pp. Price, \$2.00.*

The ambitions and difficult purpose and plan of this book as set forth in the preface should be fully accomplished:

The school's program of safeguarding the health of the child devolves chiefly upon the teacher and for her this book is primarily written. In it the study and practice of health essentials are made matters of everyday living, something the pupil can understand and use, for the principles that govern health are, in themselves, of little value to him unless he is trained to appreciate them and to put them into practice. . . . How health instruction may often be correlated with lessons in history, geography and other subjects is pointed out.

Each chapter is divided into two distinct parts. The first gives a concise, accurate and very readable statement on a single subject concerning health; the second provides detailed instructions how to put the idea across to the child. The suggested pictures, tricks, games, booklets, posters, diagrams, slogans and "healthgrams" are clever, well illustrated and should be effective in the hands of a conscientious teacher. It is evident that the author realizes the fact that physiology "as a subject to be studied from the point of view of animal and mineral matter is usually uninteresting to healthy, active, carefree boys and girls," and makes every effort to teach "positive health" and the "why" of hygiene.

The most up-to-date knowledge of all branches of public and private health, including ventilation, serum treatments, mental hygiene, and even sanitary engineering and community health programs, is presented in attractive form with a constant emphasis upon keeping well rather than preventing disease. In fact the teacher is warned to avoid too much zeal in presenting the details of germs and sickness because "wherever we begin trying to be 100 per cent perfect in health matters, there is a danger of de-

veloping notions about disease which may finally affect us as unfavorably as would the disease itself." The teacher is also frequently admonished to practice what is preached and to give due heed to her own health both for the sake of herself and the effects upon her pupils.

The information presented is simple and accurate. We are given the story of the Chinese doctors who for centuries have been paid for keeping people well. There appears to be no basis of fact in this legend, but it so well illustrates the point as to be almost justifiable—like poetic license.

The suggested classroom methods are evidently designed for children in the lower grades. There is no reason why the more advanced half of the book could not be separated, illustrated and made a textbook for high school and a handbook on health for the public. Each chapter is followed by references for further reading which makes it possible to go into every subject in greater detail.

This book should be of real value not only to teachers but also to those public health workers whose duty it is to present their cause to the public in simple, graphic form.

JOHN HALL

Gewinnung und Kontrolle der Trinkmilch—Von *Dr. H. H. Boysen. Verlag der Molkerei-Zeitung. Hildesheim: 1929. 77 pp. Price, \$50.*

This is a booklet in which an attempt has been made to emphasize the important facts concerning the production and control of milk supplies from a hygienic standpoint. More than half of the book is devoted to a translation into German of portions of *Standard Methods of Milk Analysis*, of the American Public Health Association. The illustrations are better than in our edition of the above. If brief and pertinent statements are desired they can be found here.

JOHN F. NORTON

The Hygiene of the School Child—
By Lewis M. Terman and John C. Almack. Boston: Houghton Mifflin, 1929. 505 pp. Price, \$2.50.

This text, designed for the use of teachers' colleges and teachers, is a thorough revision of a text issued fifteen years ago under the sole authorship of Dr. Lewis M. Terman.

It is divided into five major parts: I—Educational Hygiene; II—The Facts and Principles of Child Growth; III—Growth Disorders, Defects, and Disease; IV—Preventive Mental Hygiene; V—Special Aspects of Educational Hygiene.

Part II should have peculiar significance to school administrators, and to those specializing in the health of children. Part III contains much material which would be peculiarly valuable to nurses and doctors interested in school health supervision, and to teachers and administrators handling special classes for handicapped children.

Part III should be read by every teacher, not only that he or she may keep abreast of this rapidly expanding field of health and education, but that the information may be used in the daily contact with pupils entrusted to them.

This valuable text should be a part of the professional library of school nurses and physicians, and of teachers and school administrators.

CHARLES H. KEENE

A Handbook of the Mosquitoes of North America. Their Structure. How They Live. How They Carry Disease. How They May be Studied. How They May be Controlled. How They May be Identified—
By Robert Matheson. Springfield, Ill.: Charles C. Thomas, 1929. Price, \$5.50.

A clear, concise treatise on the North American mosquitoes, especially well organized for the student. The first

four chapters on Characteristics of Mosquitoes, Biology of Mosquitoes, Mosquitoes in Relation to Human Welfare and the Problem of Mosquito Reduction, will prove most valuable to the practitioner. The last three chapters, on collecting and classification, are a little beyond the average practitioner, though very well presented for the systematic student of mosquitoes.

The photographs of breeding places and illustrations of anatomical structures are unusually good. The book is beautifully printed and put together.

L. HASEMAN

Health Heroes. Edward Livingston Trudeau—
By Grace T. Hallock and C. E. Turner. New York: Heath, 1929. 168 pp. Price, \$1.12.

The outstanding characteristics of Trudeau, the beloved physician, were his altruism and optimism. These are traits which have marked most of the really great sanitarians. Like Trudeau, such leaders as Sedgwick, Reed, Gorgas, and Vaughan, were invariably gentle, courteous, considerate, and always thoughtful of others. These men were not lacking in force and determination, but they were fair, they were humane, and they seldom displayed those disagreeable qualities which sometimes impair the rest of us.

It is highly desirable that school children, especially those at the impressionable age of adolescence, should read about men with ideals such as those possessed by Trudeau.

This little book is written in a pleasing style, with a fine sympathetic appreciation of the friendly physician of Saranac, who lived an inspiring life of self sacrifice. There may be some stimulation in conflict, but after all, there is greater inspiration in a career which could produce the love, regard, and respect of all fellow-men. This book can be highly recommended for its purpose.

JAMES A. TOBEY

The Biological Basis of Human Nature—By *H. S. Jennings*. *New York: W. W. Norton and Co., 1930.* 384 pp. 51 ill. Price, \$4.00.

With modern reforms and reformers running rampant, each basing his gospel on partial information, there is need for an authoritative treatment of the subject of genetics which can be easily understood. Both aspects of this need have been very happily filled by Professor Jennings. His authority cannot be questioned, and his treatment leaves little to be desired.

In many ways he is very fortunate in his subject. Genetics can be made popular with few or none of the drastic popularizing expedients necessary in treating such subjects as relativity or quantum mechanics. The data are obtained by direct observation on systems furnished to order by nature, and the results can be formulated with the employment of a minimum of inference requiring anything like subtle deduction. Hence most laymen possessing the patience required to acquaint themselves with the available data should have no trouble in becoming oriented to a scientific genetic point of view.

Furthermore the appeal of this field is very general. The direct application of the results of genetic studies in the consideration of the problems of eugenics, of specific sociological reforms such as prison reform, of behaviorism, of the mechanism of evolution, of the ethics and philosophy of medicine, lends to it a general interest. In fact there seems a possible bearing even on such speculative ideas as reincarnation. The author has recognized these applications, and each type of evangel can find the bearing of genetics on his particular prejudice sympathetically but impersonally treated.

This type of treatment lends to the volume the character of a well coördinated series of essays. The bulk of each essay is in answer to a series of

direct questions propounded by the author, the first essay, five chapters in length, laying the informational foundation in the science upon which subsequent discussions and applications are based.

Chapter IX deals with "Biological Fallacies and Human Affairs." In it there are listed and discussed some fourteen types of fallacy which may be implicit in the interpretation of experimental work of otherwise high enough caliber. While these are labelled biological fallacies and are all applicable in that field, there are only a few which are so restricted, and this one chapter might well be read with much profit by workers in any field of activity which employs a scientific method.

In the final chapter the author seems to descend from his general high level of treatment, and, in urging the acceptance of the doctrine of emergence as a methodological point of view for workers in biology, uses a type of reasoning which seems to smack of some of the same fallacies he has previously pointed out as underlying the conclusions of certain workers that acquired characters are inherited in the Lamarckian sense. His reason for this stand seems to be summed up in the statement that "the doctrine of emergent evolution is a declaration of independence for biology." The point of view of emergence seems, then, not so much a productive methodology as a desire for a psychic sense of autonomy in biology. The ease with which emergence permits *ad hoc* rationalizations of data, regardless of how complete the picture furnished by the data, would seem to be a high price to pay for such a psychic sense even were such an attitude necessary to the mental happiness of the worker and not justified by any other point of view. It is certainly questionable whether the welfare of biology is bound up in its independence.

The reviewer can conceive of no class

of thinking individuals, not even excluding geneticists, who would not find this volume of extreme interest.

ALLEN E. STEARN

A Textbook of Physiology for Nurses—By *W. G. Christian, M.D., and C. C. Haskell, M.D.* St. Louis: Mosby, 1929. 153 pp. Price, \$2.00.

The authors of this volume have treated physiology in a very elementary manner, and in so doing they have made many unavoidably ambiguous statements. The subject matter is not new, as stated in the introduction, but merely condensed and simplified from authentic textbooks.

A book of this type will not fit into the already overcrowded curriculum of the nurses' training schools. The book is not complete enough to meet the requirements of an adequate physiology course. The present trend is to combine anatomy and physiology into one course. In this combination the nurse is given the fundamental knowledge of the two subjects, first, by studying the anatomical structure, and second, by associating the physiology or function of the structure in the body.

Nurses entering training schools for the most part are without previous training in chemistry, which excludes from their comprehension many of the good points of this book. A good textbook of anatomy and physiology includes a greater part of the elementary physiology than this book has to offer.

HOWARD C. COGGESHALL

The Health Care of the Baby—By *Louis Fischer, M.D.* New York: Funk & Wagnalls, 1930. 248 pp. Price, \$1.00.

This is a very practical handbook for mothers in which the advice for feeding, first aid, and "what to do until the

doctor comes" is presented in simple language. There are also a number of good recipes.

The chapter on Bad Habits is the weakest in the book. The author is apparently unaware of the recent literature on this subject. This difficulty might easily be offset by supplementing the book with publications on sex and mental hygiene from the Children's Bureau at Washington. DAVID M. LEVY

A Health Revue—A Pageant of Health Activities and Rules Adapted for Junior High Schools—By *Margaret Strassler. Introduction by T. M. Muir.* New York: Barnes, 1930. 75 pp. Price, \$1.50.

It is the execution rather than the idea that makes *A Health Revue* a novel and useful addition to the literature on entertainment as a form of health education.

Milk bottles have chased coffee pots before. Queens and courtiers have long given audience to personified carrots and apples. Tooth brush drills are commonplace. However, this revue in which the familiar ten rules of personal hygiene for boys and girls are made a part of a colorful pageant was produced on a grand scale. The household arts department, physical education and arts all worked hard on its preparation. The performance must have been a finished piece of stagecraft. A careful record is set down in this book written by Margaret Strassler. Pictures, diagrams and exact instructions cover every detail so that a junior high school health education department in any part of the country should be able to reproduce faithfully the 3' x 5' cake of soap, the Egyptian dance, the drills, the stage lighting and the costumes.

MARY SWAIN ROUTZAHN

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Typhoid Fever Rates—The annual summary of typhoid fever rates of the country evidences again the continued decline of this disease.

ANON. Typhoid in the Large Cities of the United States in 1929. *J. A. M. A.*, 94, 20: 1574 (May 17), 1930.

Infant Deaths and Health Expenditures—No demonstrable relationship was found between infant mortality rates and per capita official expenditures for various health services in the statistics included in this study.

BOLT, R. A. Municipal Expenditures for Public Health in Cities of the United States of 70,000 Population and Over for the Year 1923 in Relation to Their Infant Mortality Rates. *Am. J. Hyg.*, 11, 3: 601 (May), 1930.

Diphtheria Immunization with Toxoid—"Toxoid should be given without preliminary testing only to children under 6 years. . . . The dilute toxoid reaction test was given to all school children." The paper is well worth reading by all sanitarians having to do with this subject, and who hasn't?

BURKE, F. S. The Administrative Control of the Diphtheria Toxoid Campaign in Toronto. *Canad. Pub. Health J.*, 21, 5: 209 (May), 1930.

Measuring Residual Chlorine—An apparatus is described which measures the residual chlorine in treated water supplies. A photo-electric cell records the degree of the color when orthotolidin is added to fresh samples of chlorinated water.

CUTLER, J. W., and GREEN, F. W. Operating Experiences with a New Automatic Residual Chlorine Recorder and Controller. *J. Am. Water Works Assn.*, 22, 6: 755 (June), 1930.

Noise—Do you want to measure the noise in your town? This paper tells

you how, and further, tells you what noise does to you.

DENNIS, E. B., JR. Noise—Its Measurement, Effect and Control. *New York State J. Med.*, 30, 10: 573 (May 15), 1930.

Cod Liver Oil and Viosterol—Another report of a study which leads to the conclusion that viosterol in the recommended dosages is less effective than cod liver oil in the prevention of rickets. Perhaps rickets is not due to a deficiency of Vitamin D alone.

DESANCTIS, A. G., and CRAIG, J. D. Comparative Value of Viosterol and Cod Liver Oil as Prophylactic Antirachitic Agents. *J. A. M. A.*, 94, 17: 1285 (Apr. 26), 1930.

Philippine Vaccination History—The ups and downs of compulsory vaccination through periods of American and native law enforcement furnishes a striking story to refute the anti-vaccinist allegations. Good ammunition.

HITCHINS, A. P. Smallpox. *Pub. Health (Mich.)*, 18, 4: 75 (Apr.), 1930.

Smallpox Vaccination—A frank discussion of the disadvantages of vaccination and a detailed account of good technic. The immunization of infants is stressed.

LEAKE, J. P. Vaccination. *New Eng. J. Med.*, 202, 20: (May 15), 1930.

Rural Health Administration—The map showing the present status of full-time rural health units will encourage sanitarians who have watched the march of this great project. The total is 505 counties in 35 states.

LUMSDEN, L. L. Extent of Rural Health Service in the United States, 1926-1930. *Pub. Health Rep.*, 45, 19: 1057 (May 9), 1930.

Prenatal Clinics in Scotland—This detailed account of the routine employed

for several years in Glasgow will prove interesting to American child hygienists.

MACCUNN, M. P., and WYLIE, M. E. Ante-Natal Care. *Med. Off.*, 43, 19: 209 (May 10), 1930.

Vitamin B Source—Wheat germ as a source of vitamin B proved to be a potent growth promoting factor when fed to undernourished children. Rolls made of 50 per cent germ and 50 per cent white flour were used as the dietetic medium.

MORGAN, A. F., and BARRY, M. M. Underweight Children. *Am. J. Dis. Child.*, 39, 5: 935 (May), 1930.

Immunization Against Disease—A straightforward, absorbing, lucid story of what is known about the prophylaxis of the several communicable diseases. An outstanding example of a talk for laymen.

PARK, W. H. Serums and Vaccines in Infectious Disease Prevention. *Child H. Bull.*, 6, 3: 73 (May), 1930.

School Children's Hearing—"In no group, at any age, when both sexes

were taken together, did the rate of children with significant hearing loss rise as high as 4 per cent." This is one of the conclusions on this experience with the audiometer.

STERLING, F. B., and BELL, E. Hearing of School Children as Measured by the Audiometer and as Related to School Work. *Pub. Health Rep.*, 45, 20: 1117 (May 16), 1930.

Cancer Research—What research has done and hopes to do in finding the cause and cure for cancer is told simply and well. The paper prepared for nurses will interest all sanitarians even though it contains little that is very new.

WOGLOM, W. H. Cancer as We Know It. *Am. J. Nurs.*, 30, 5: 543 (May), 1930.

Cancer and Mineral Oils—Liquid petrolatum painted on skin of, and fed to, susceptible albino mice produced no cancer. No evidence was found to indicate any danger in the therapeutic use of mineral oils.

WOOD, F. C. The Non-carcinogenic Nature of Purified Mineral Oil. *J. A. M. A.*, 94, 21: 1641 (May 24), 1930.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Sweden—Report of Official Committee on Maternity Welfare Work—The committee of experts appointed by the Social Welfare Department of Sweden in 1926 for the study of maternity-welfare measures issued its report at the end of 1929.

Although acknowledging that maternity welfare work is well developed in Sweden, the committee pointed out the need for improvement. In addition to educational measures of various kinds, better medical care and financial aid were recommended for the expectant mother, the woman in confinement, and the young mother caring for her child.

To improve the medical care, the committee suggests an increase in the facilities for medical examination of and advice to expectant mothers and mothers of young babies. Such examinations are given now only in some cities, but they should be given more generally and more regularly. In smaller communities this work can be performed by the midwives in public service * but in towns and cities there should be a separate organ, a "bureau for the protection of mothers and children." In the opinion of the committee, some of the existing child welfare agencies could take over this function. For the examinations and advice the midwife should be paid one-half by the mother, the other half by public funds. For the supervision of the care of new-born children, the committee advises the enlistment of the services of the public health officers, the midwives to report the cases of childbirth to the officers who would supervise the new-born infants in their districts.

The committee recommends an increase in the number of beds for mater-

nity cases and the establishment of special maternity hospitals which are to be aided financially by the State, also an increase in the number of homes where expectant mothers unable to work and mothers with infants can find shelter. There is also need for a larger number of visiting housekeepers.

As to the financial aid to mothers, two laws are proposed. One law provides for maternity benefits of 50 kronor (about \$13.40) to be paid on application to women whose income is below a certain specified amount. In such cases midwife service is also to be given. The other proposed law provides a maternity benefit equal to two-thirds of the wages of women in certain occupations to compensate them for the loss of earnings caused by the law prohibiting the employment of women in those occupations for 6 weeks after childbirth. The committee recommends that most of the expenses be met by the State. It also urges close coöperation between the various child welfare agencies.—*Sociala Meddelanden*, Stockholm, 12: 986, 1929.

Let There Be Sight—That an annual report may be attractive, interesting, and enlightening is demonstrated by the National Society for the Prevention of Blindness in its 15th annual record for 1929. An unusually attractive cover arouses interest and prompts one to look inside. Here one finds an excellent photograph of a boy and girl over the caption Healthy, Happy Eyes of Childhood. The table of contents, under the title of the report Let There Be Sight, carries the following section headings: Through Preventing Eye Troubles in Babies; Caring for the Eyes of Preschool Children; Conserving the Sight of School Children; Conserving the Sight of the Worker; Research and

* In many communities of Sweden midwives are employed by the local government on a salary in order to assure their presence; in addition the patients also pay a certain fee.

Demonstration Projects; Public Education; Coöperation with Other Agencies; Financial Support.

The report is well printed in good type, on paper well adapted to the use of excellent photographs and diagrams which illustrate material in the descriptive text. The incidence of ophthalmia neonatorum in new pupils in schools for the blind for the year 1929 was reported by the American Foundation for the Blind to be 9.5 per cent, a reduction of such incidence to the extent of more than two-thirds in the past 21 years. The importance of effecting the cure of syphilis in the expectant mother or in the father in order to prevent a large percentage of blindness is being increasingly realized by the National Society and by agencies interested in the prevention and cure of venereal disease.

Studies of eyes of preschool children are reported as showing that of 982 tested, 21 per cent had some abnormal condition of the eye. During the year, 92 communities in 12 states and Canada were given demonstrations and general talks on prevention of blindness. The organization of sight-saving classes in schools is described. Specific projects to aid the worker are outlined, as well as research and demonstration projects. The National Society educational campaign included the circulation of about 725,000 pieces of literature, extensive use of charts and exhibits, and 307 lectures which reached an aggregate audience of some 45,000 people.

Copies may be secured upon application to the Society, 370 Seventh Ave., New York, N. Y.

Lincoln, Neb.—The 1929 report shows a per capita expenditure by the Health Department of 68 cents. A birth rate of 18.6 and a death rate of 12.9 are recorded. A marked increase in the number of prenatal patients cared for in the General Clinic of the Health Department is noted. Eighteen hun-

dred and fifty-four visits were made during the year to the clinic.

The daily average amount of milk sold in the city was 0.82 pint per capita, based on a population of 70,000. There were 1,189 inspections made of milk plants, 12 of creameries, 194 of ice cream plants, and 939 of dairy farms.

Colorado Springs, Colo.—A total of \$27,013 was expended in 1929 by the Colorado Springs Department of Health and Sanitation, which, on an estimate of a population of 36,000, is \$.75 per capita. Sixteen per cent of the budget was for general salaries, 18.5 per cent for medical work for school children, and approximately 10 per cent each for milk control, sanitary work, and communicable disease control. The resident death rate was 14.2 per 1,000, which is lowered to 11.9 when deaths due to tuberculosis contracted elsewhere are excluded. Four typhoid fever deaths were the result of an epidemic of 37 cases due to a raw milk supply.

The report of 39 pages contains several illustrations of Colorado Springs scenery, which tends to fulfil for the interior the promising impression made by an attractive red cover.

Ottawa, Can.—Ottawa's outstanding public health occurrence of 1929 was an epidemic of poliomyelitis. The first reported case appeared July 28 in the western part of the city, followed by 3 other cases within the week. The following week 7 were reported, and the week after 1, which indicated a decline in incidence. However, the fourth week showed 16 cases and was followed by 11 to 25 cases per week until late in October. In all, 176 cases were reported with 3 deaths. The age of the patients ranged from 7 months to 25 years, averaging 7.4 years. In only 4 instances were 2 cases reported from the same premises.

As the outbreak was not entirely un-

expected, the health department had prepared a partial list of donors in case of need. Convalescent serum was thus immediately in hand, but in limited amount. This was later supplemented by advertising in the local papers. Daily press articles, the circularizing of physicians, and the calling of a Medical Society meeting formed the publicity, and to improve early diagnosis and reporting, a necessity if the serum treatment was to be successful. In all, 141 cases, or 80 per cent, were hospitalized. Of these, 26 had paralysis on admission. Of the remaining 115 cases, which were given serum treatment, 109, or 95 per cent, recovered completely, 5, or 4.3 per cent, recovered with paralysis, and 1 died. During the first 4 weeks of the epidemic, 23 cases were hospitalized; of these, 17 had terminal paralysis (14 on admission). Of the subsequent 118 cases, 8 had paralysis on admission.

The general death rate from all causes of death for the year was 14.1 per 1,000. The birth rate is the lowest recorded. Infant mortality (118.6) was higher than in 1928, due chiefly to respiratory diseases. The tuberculosis rate was low, 59.9 per 100,000 population. Chicken pox and measles were prevalent during the year.

Greenwich, Conn.—The health officer's report for 1929 is contained in the town report and outlines in a comprehensive manner the health program of this community. This report is of more than usual interest because it traces the history of the health department, and of health legislation, and indicates the important place which public health occupies as an official governmental function. The expenditures by the Board of Health last year amounted to \$56,699, while receipts totalled \$773.

There are 4 health stations under the department where prenatal, infant and preschool conferences are held. Greenwich has a Department of Public Health

Nursing with a supervisor under whom all the public health nurses in town, including school nurses, function.

New Jersey Sanatoriums—A comprehensive study has been made of tuberculosis patients in New Jersey sanatoriums by the State Department of Institutions and Agencies. In the 25-year period 1904–1929, the death rate from tuberculosis in New Jersey has dropped from 179.5 per 100,000 in 1904 to 74.9 in 1929. Most of the sanatoriums of the counties have been built during the last 20 years and are continually increasing their capacities. Preventorium during the last few years have proved their part in the declining rate by curing children who have been contact cases and who may have a slight trace of tuberculosis. The important part played by state and county tuberculosis leagues and clinics is indicated.

The 5,204 new cases reported to the State Board of Health in 1929 and the 2,917 deaths, together with the 20,000 active cases of tuberculosis on record in the files of the state department, indicate that here as elsewhere are problems still to be solved. Forty-two per cent of the patients entering sanatoriums for the first time are between the ages 15 and 29, and 15 per cent of the females entering are between 15 and 19 years of age. During last year, 41 per cent of the pulmonary cases entered in the far advanced stage, with the same proportion moderately advanced, and 18 per cent in the minimal stages of the disease. Of the patients in sanatoriums, 15 per cent of those discharged remained less than 1 month, 27 per cent less than 2 months, and 38 per cent less than 3 months.

There are 11 county and 1 state sanatoriums. A new children's unit of 114 beds provides preventorium care for children 5 years of age or over, and increases the capacity at Glen Gardner to 377. A 50 per cent increase in the

number of persons in state and county sanatoriums from 32 to 48 per 100,000 population has occurred during the past 10 years. The actual numbers have risen from 996 to 1,887. This means, in view of the decreasing death rate, that better facilities for discovery and treatment have been provided. Tables are presented to show as arrested, apparently arrested, or quiescent, 51 per cent of those discharged who entered with minimal tuberculosis, as contrasted with 31 per cent discharged of those entering with moderately advanced tuberculosis, and only 16 per cent discharged of those entering with far advanced tuberculosis.

Detroit, Mich.—“Personal Health is Public Wealth,” is the title of Detroit's 1929 report published in the January, 1930, *Bulletin* of the Department of Health. Detroit's population growth from 465,766 in 1910 to 1,429,200 in 1929 is shown at the outset in tabular form by years. Many excellent charts and statistical tables add interest to this comprehensive report of 68 pages. The last page shows in a table the distribution of the Department of Health personnel of 727 members, exclusive of the 925 employees in the city hospital and the sanatorium, and the 22 sanitary police, on the police pay roll.

A unique and carefully worked out plan of diphtheria prevention is described. In 1928 it was felt that diphtheria prevention had been demonstrated over a sufficient period of time for the majority of people to have confidence in it. Hence, the work was in November, 1928, turned over to the practicing physicians of the city according to a plan worked out by the Public Health Committee of the County Medical Society and the Department of Health and approved by the County Medical Society.

Weekly meetings were held during the year by the Public Health Commit-

tee of the Medical Society, at which time representatives of the Department of Health discussed with the committee points of mutual interest and devised plans for meeting specific problems. An immune serum clinic was developed, where blood was taken from donors who had within one year recovered from scarlet fever, measles, poliomyelitis, meningitis, whooping cough, chicken pox and mumps and the immune serum was prepared for distribution to physicians.

The principal causes of death were heart disease (13.6 deaths per 100,000 population), pneumonia (10.3), tuberculosis (8.0), violence (7.6), early infancy (7.2), and cancer (6.8). A birth rate of 23.5 and an infant mortality rate of 69.4 are noted.

In connection with school health work, the Department of Health, through its staff of school physicians and nurses, attempts to see to it that parents and children alike are properly instructed so as to avail themselves of the help of their own physicians and dentists for these services.

An effort was made to evaluate the work in elementary grades. Examinations of all children in all secondary schools showed that while of all 1st grade children there were 69.7 per cent with defects, in the intermediate group the figure dropped to 46.8 per cent, and in the high schools, to 39 per cent. A health counsellor program was set up by the Board of Education in certain schools under the supervision of a full-time head, who was charged with the guidance of the individual and with the arrangement of the activities of the school itself to help meet the needs of the child.

Newport, R. I.—Newport, R. I., had an estimated population in 1929 of 30,600. The per capita expenditure for health was 71 cents. The staff of the Board of Health consists of a commissioner, clerk, bacteriologist, milk and

sanitary and food inspectors, a school nurse, a part-time oculist and aurist, a part-time chief, 2 assistant dental inspectors, and 4 part-time medical school inspectors. Of 5,539 pupils examined, 617 were found with defects in vision and 149 in hearing. There were 536 pupils registered in the dental clinic, of which 235 received prophylactic treatments and 221 were referred to other dentists. The school nurse made 1,605 visits, as well as assisting in the Dental Clinic and in the eyesight and hearing examinations and with the Schick tests

and treatments in the schools and at the office.

For 11 full years regulations have been enforced permitting the sale of but two classes of milk—certified and pasteurized. This condition has doubtless been a factor in placing Newport among the low infant mortality cities of the country, the 1929 estimated rate being 38.7 per 1,000 births. Only 21 infant deaths from gastroenteric disorders have been reported in the 11 years since enforcement, as against 118 in the 11 previous years.

NEWS FROM THE FIELD

HOSPITAL ASSOCIATION MEETING IN NEW ORLEANS

THE American Protestant Hospital Association will convene in New Orleans on October 17, 1930, and will continue in session until October 20, 1930, when the preliminary meetings of the American Hospital Association will begin. They will continue through October 24. The American Occupational Therapy Association, the Hospital Social Workers' Association and the Association of Children's Hospitals will hold their meetings at the same time.

The American Public Health Association meets at Fort Worth, Texas, the following week.

INFANT MORTALITY RATE HIGHEST IN WASHINGTON

THE National capital has the highest infant death rate in the country—19.2 per 1,000 under 1 day old, as compared with an average of 15 per 1,000—according to Drs. Leon S. Gordon and Oscar B. Hunter, Washington.

They made this statement before the District Medical Society on May 7.

CLEVELAND ACADEMY OF MEDICINE

THE Academy has embarked upon a career of editorship of a health column in the Cleveland Press. For several years the Committee on Health Education has discussed with the Cleveland newspapers the possibility of furnishing such a column. As an experiment the *Cleveland Press* accepted a series of brief articles on general health subjects now appearing under the heading "Your Health Today" on Mondays, Wednesdays and Fridays.

The column is being supplied by the Committee on Health Education and H.

Van Y. Caldwell, executive secretary. Dr. S. C. Lind has been named as consulting editor, and will work with Mr. Caldwell on the revision of all material submitted.

The members of the committee are: Drs. Lester Taylor, Chairman, R. A. Bolt, A. B. Denison, C. G. LaRocco, S. C. Lind, E. A. Peterson, H. D. Piercy and H. L. Rockwood.

CANADIAN PEOPLE VALUED AT \$175,000,000,000

VALUATION of the Canadian people as human beings at \$175,000,000,000 was made before a joint meeting of the Canadian Public Health Association and Ontario health officers by R. H. Roats, Dominion statistician. He explained the basis of the estimate by giving the figures of value in the case of a man able to earn \$2,500 a year at the height of his working ability.

At birth, he said, such a man is worth \$9,000; at 15 years, \$25,000, and at 25 years, \$32,000. Value of the female life, he said, was half as much.

"That," he explained, "is the capital value of the asset. It is your professional duty to maintain it at its maximum of efficiency and dividend earning capacity."

PHILIPPINE UNIVERSITY RECEIVES \$150,000 GIFT

A GIFT of \$150,000 by the Rockefeller Foundation to the University of the Philippines, a State-owned institution in Manila, has been announced by Eugene A. Gilmore, Vice-Governor-General of the Philippine Islands. The fund is for the construction of a building to house the university's graduate school of hygiene and public health.

Mr. Gilmore said the gift was made on condition that the university provide a suitable site and yearly operating budget of \$40,000. These conditions, he said, have been met and the money has been given.

INTERNATIONAL ASSOCIATION OF MILK DEALERS

ONE hundred and thirty laboratory directors and workers from the East assembled at Geneva (N. Y.) Agricultural Experiment Station on April 29 to participate in an intensive two-day laboratory clinic.

One of the most interesting discussions was on recent research and discoveries in dairy chemistry with special reference to the caseins of milk. Dr. D. C. Carpenter of the Station led the discussion. He has recently done outstanding work in coöperation with Dr. Svedberg of Sweden.

Dr. R. S. Breed and Dr. A. C. Dahlberg outlined the work that is now in progress at Geneva.

Among the interesting papers was one by A. J. Powers of Borden Company, which discussed standard plate methods. It was shown that sample bottles, sampling procedure and plating technic were not entirely standard although standard ingredients for media had solved numerous media problems.

SANITARY SURVEY OF TEXAS STORM AREA

ON May 6, a number of storms developed over Texas with cyclonic intensity. Much damage was done, particularly in a 20-mile strip of 200 yards width, southwest of San Antonio and in similar areas in Central Texas. The City of Frost suffered the worst. This city has a population of 1,100. About 60 of the 200 homes were destroyed.

In all there were 65 deaths, 22 of them being in Frost, and many were injured. A hurried review revealed that the water supply with its sources from

a deep well was considered of satisfactory quality. With no power the pumps were out of commission; this with the broken taps soon emptied the reservoir. Power was restored in 24 hours but pressure could not be maintained because of broken connections. Plumbers were rushed to the locality; samples were tested daily; apparatus for emergency supply of chlorine was made available; and instructions were issued to boil all water.

Because of broken connections, and lack of running water, sewage disposal was considerably retarded, but temporary latrines in the form of pit toilets were installed to take care of the large number of workmen needed in reconstruction, and until regular service could be restored.

Temporary canteens were established with special sanitary inspectors to supervise sanitary measures.

The State Department of Highways took care of the cleaning of streets and disposal of refuse, dead stock, etc.

A temporary clinic was opened under the direction of local health officers with the assistance of the State Health Department and the Red Cross.

Several other areas were reached as quickly as possible with precautionary measures, and instructions were published in all newspapers on the prevention of diseases arising from the storm. —E. G. Eggert, Sanitary Engineer in Charge.

NEW JERSEY INDUSTRIAL NURSES

THE Industrial Nurses Club of New Jersey met on May 19 in Newark, N. J. There was a dinner after which there was a round table discussion.

NEW LABORATORY CAR

THE Southern Pacific car mentioned in the June *Journal* should have as its personnel a laboratory technician, a doctor, and probably a dentist. The car is of regulation Pullman length and

is beautiful in its interior appointments, being of rather extraordinary mahogany. It has two staterooms with bath between, a compartment, and two compartments for the crew of two, the cook and porter, with their bath and toilet. The car is intended to do periodical physical examinations, especially in inaccessible parts of the Southern Pacific system and endeavor to sell the idea to their men and for their families as well. It will be equipped with movies of an educational type on all subjects of preventive medicine. It will also be equipped with movies for the medical staff of the railroad and it is expected not only to do periodical examinations but will offer immunization against disease for both employees and their families. It has a complete X-ray equipment with its own unit of batteries and gasoline engine. There is a completely equipped darkroom and bacteriological and chemical laboratory. The car will be available for any epidemiological work, especially at the time of any epidemic. There are an observation platform, an observation waiting room which can be turned into a dining room en route, and an examining room for various types of examinations.—Dr. J. C. Geiger (see also *A. J. P. H.*, June, 1930, p. 694).

FELLOWSHIPS IN MEDICINE

THE issue of the *Journal of the Association of American Medical Colleges* for January, 1930, contains a list of fellowships, funds and prizes available for graduate work in the United States and Canada. A reprint, which has been made available by the Editor of this *Journal*, should prove of interest to health administrators who are in search of a list of available fellowships.

A NEW FOUNDATION

THE Josiah Macy, Jr., Foundation, incorporated in New York State and established through an initial gift

of five million dollars from Mrs. Walter G. Ladd in memory of her father, will devote its income to the support of studies of fundamental aspects of "health, sickness and methods for the relief of suffering."

It will offer aid in form of scholarships, awards, publications and financial grants to promote coöperation with unified aims between universities, colleges, hospitals, laboratories, learned societies and other undertakings of social usefulness.

THE HEALTH LIBRARY OF THE CITY HALL

THIRTY books on various phases of public health which ought to form the nucleus of a health library in every city hall are described in some detail in an article in the 1930 *Municipal Index*, published by the *American City Magazine* of New York. This useful bibliography has been prepared by Dr. R. S. Patterson, who edits the "Selected Public Health Bibliography" in the *American Journal of Public Health*, and by Dr. James A. Tobey, who is contributing public health editor of the *American City Magazine*. Health officers will find the suggestions in this article of great value.

MATERNITY AND CHILD WELFARE

THE National Conference on Maternity and Child Welfare will be held at the Friends' House, Euston Road, London, on July 1, 2 and 3.

The Presidential Address will be delivered by Susan Lawrence, M.P., Parliamentary Secretary to the Minister of Health. This is the first time since the series of Conferences was inaugurated in 1906 that a woman has played this important, but very appropriate, rôle. Among the Chairmen of the various sessions will be: Sir Arthur Stanley, The Lady Lawrence and Neville Chamberlain.

PERSONALS

- DR. C. V. MERRITT, for a number of years Health Officer of Flint, Mich., died recently and has been succeeded by Dr. C. J. Scavarda.
- DR. JOHN SUNDWALL, Director of the Department of Hygiene and Public Health of the University of Michigan, will teach at the University of California during the summer session.
- DR. J. J. DURRETT, who resigned his position as chief of drug control, Food and Drug Administration, U. S. Department of Agriculture, to become State Health Officer of Alabama, has returned to the former position.
- W. C. RUCKER, M.D., of the U. S. Public Health Service, New Orleans, died on May 22.
- FRED N. JOHNSON has been named sanitary officer of Cumberland County, Tenn., to succeed W. H. Wright, who recently resigned.
- E. C. STOV, of the U. S. Public Health Service, who has been assigned to work in Tennessee for the past several years, has gone to Florida, where he will work in connection with the Florida State Board of Health.
- DR. MORRIS MASLON was recently re-appointed to the Glens Falls (N. Y.) Board of Health.
- DR. NATHAN M. SPECTOR has been appointed Health Officer of Willimantic, Conn.
- DR. WALTER P. McGRATH has been elected as Health Officer of Menasha, Wis.
- DR. GUSTAV J. HILDEBRAND has been elected Health Officer of Sheboygan, Wis.
- DR. WILLIAM B. HARRISON has resigned his position as Health Officer of Shelby County, Tenn., and is now affiliated with the Tennessee State Department of Health. Dr. Wallace P. Moore, formerly director of the division of epidemiology of the county health department, replaces Dr. Harrison as County Health Officer.
- DR. E. G. SMITH, dental clinician, has been added to the staff of the Tennessee State Department of Public Health. Dr. Smith is in charge of the state dental program, and will make his headquarters for the present in Nashville. Later he is to be assigned to East Tennessee, with headquarters at Knoxville.
- DR. L. M. COULTER was appointed Health Officer of Stanislaus County, Calif.
- M. T. S. WRIGHT is City Health Officer of Dunsmuir, Calif. He succeeds John H. Young.

CONFERENCES

- August 26-28, Eighth Texas Sanitarians Short School, held with Texas State Department of Health and the City of Amarillo, Amarillo, Tex.
- September 8-12, American Congress of Physical Therapy, St. Louis, Mo.
- September 29, week, National Safety Council, Chicago, Ill.

Significance of Thermophilic Bacteria in Pasteurized Milk*

L. A. ROGERS, D. SC., AND W. C. FRAZIER, PH. D.

Dairy Research Laboratories, U. S. Department of Agriculture, Washington, D. C.

IN discussing this subject we feel that it is best to attempt to answer certain questions which probably exist, or have existed at some time, in the mind of everyone concerned with the control of city milk.

What are thermophilic bacteria? It may not be necessary to go into detail, but it is well to define rather exactly what we propose to discuss. We shall include not only the obligate thermophiles which grow only at temperatures above the usual limits of bacterial growth but also the facultative thermophiles which grow normally at ordinary temperatures and are able to multiply at 50° C. or higher.

There are no natural limits for these groups. The obligate thermophiles have a temperature range running as high as 85° C. Some facultative thermophiles grow as low as 20° C. and as high as 60° C. We are interested in those which grow at the usual pasteurizing temperatures and those which are unable to grow at this temperature but grow readily at a few degrees below this point.

The upper thermal limit of the growth of any particular strain of bacteria is much more sharply defined than the lower. Bacteria which are inhibited or destroyed at 145° F. may grow rapidly at 140° F.

The thermo-resistant bacteria which, although they do not form spores, survive pasteurization, should not be confused with the thermophiles. Both groups of bacteria sometimes produce pinpoint colonies on agar plates but otherwise there is no connection between them.

There has been a tendency to look upon the thermophiles as a natural group of related bacteria. On the contrary it is a hetero-

* Read at a Joint Session of the Food, Drugs and Nutrition and Public Health Engineering Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

geneous collection including representatives of many unrelated species. They should be regarded as variants which may occur in any species and which usually differ from the normal only in their ability to grow at high temperatures.

We find among the thermophiles representatives of the streptococci, the lactobacilli, the colon group, anaerobic, and especially aerobic spore-forming rods. The last is the group most commonly found in pasteurized milk.

What is the source of thermophiles in milk? They occur naturally under conditions which make it easy to account for their presence in milk. Thermophilic bacteria were first observed in thermal springs where they sometimes grow at temperatures over 80° C. They are known to occur in fermenting manure and other vegetable material. It would probably be possible to isolate thermophiles from almost any sample of cow manure. From these sources they become widely distributed and may be found in soil, dust, on the leaves of plants, and the surface of any exposed material.

Under some conditions the surface of the soil may reach temperatures high enough to favor the growth of thermophiles and it is possible that under some circumstances they may grow in the soil at relatively low temperatures.

We consider it very improbable that bacteria of this type ever actually live in the udder. It is true that milk drawn direct from the udder into test tubes and held at 50 or 55° C. will sometimes reduce litmus, but it does not necessarily follow that this milk is inoculated with thermophiles from the ducts of the udder. Very rigid precautions are necessary positively to exclude outside contamination. However, there are many things beside bacteria which reduce methylene blue and this reaction cannot be accepted as proof of bacterial growth without proper checks.

We have examined the udders of a large number of cows without securing any positive evidence of the presence of thermophilic bacteria. However, it is not necessary to assume that these bacteria grow in the udder to account for their almost universal presence in mixed herd milk. It is probable that almost any sample of mixed milk from the ordinary farm if held at 50–55° C. would show development of thermophiles.

Under what conditions do thermophiles attain high numbers in pasteurized milk? There are a number of conditions which may work singly or jointly to produce this result. One is an exceptionally high initial contamination before pasteurization. The milk from some individual farm may come to the pasteurizing plant heavily infected

with thermophiles. This is not common but in one plant investigated it was found that the milk from one farm gave a nearly pure culture of thermophilic bacteria.

The milk may be inoculated before pasteurization by adding to the batch milk returned from the wagons. If, as frequently happens, the end of the previous day's run was high in thermophiles, this may serve as an inoculation for the new run.

The milk may be inoculated from defective equipment, such as leaks which permit milk to stand in the lining of the vat and subsequently, when highly charged with thermophiles, to seep out into the pasteurizer.

The milk may also become infected from the foam and residue left from the previous batch. Thermophiles may also multiply in the pasteurizer when some part of the milk is not maintained at the proper temperature. The reduction of the pasteurizing temperature even a few degrees brings the milk within the growth range of many varieties which cannot grow at 145° F. This may happen in dead ends of pipes, possibly in corners of vats not reached by the agitators, and especially in the foam. It is well known that the foam is several degrees lower in temperature than the milk under it and not only do the more resistant bacteria carried by the foam survive, but it acts as an incubator for many types of thermophilic bacteria.

The most common cause of high thermophilic counts is the building up in numbers when successive batches are pasteurized in the same vat without adequate cleaning between runs. There is some

TABLE I

INCREASE IN THERMOPHILIC BACTERIA IN PASTEURIZER VATS

Vat No.	Run	Reduction Time at 55° C.		Direct Counts of Streptobacilli	
		Before Past. Hrs.: Min.	After Past. Hrs.: Min.	Before Past.	After Past.
I	1	8:41	8:01	20,000	20,000
	2	6:59	4:38	42,000	345,000
	3	6:09	1:18	121,000	4,500,000
	4	2:58	0:18	1,850,000	22,000,000
II	1	1:57	0:33	1,420,000	15,500,000
	2	2:34	0:48	515,000	8,760,000
	3	6:10 (Neg.)	1:26	30,000	4,850,000

* Milk held in vat for 50 min. at 143° C.

multiplication in the first batch, started by the thermophiles which are almost invariably present in mixed milk. The foam and milk left in the bottom of the vat serve as an inoculation for the following run so that if five or six batches of milk are pasteurized in one vat the later ones are likely to have a high count. In Table I is shown how the bacteria which grow at high temperatures may grow in the vats and build up in numbers by the end of the last run of the day. The experiments were conducted in a large milk plant under normal plant conditions.

An examination of the results in Vat I shows a smooth and regular building up of thermophiles from very few after the first run to 22,000,000 at the end of the fourth. It will be noted that the reduction times correspond very well with the numbers of bacteria.

Vat II is an example of apparently bad contamination with thermophiles before the first run. The vat had evidently not been properly cleaned and scalded before the beginning of the day's run. This heavy initial contamination was reduced to some extent after several successive flushings with vats of milk but had started to build up again by the end of the day as is evidenced by the increase to 14,000,000 at the end of the fourth run.

Vat III shows a building up process for the first four runs of the day when the normal procedure was being carried out in the pasteurization of the milk. At the time of the fifth run, however, there was a break-down in the bottler and the milk had to be held for a longer time at 143° F. before the vat could be drained onto the cooler. In this case the milk was held over 50 minutes at pasteurizing temperature. The result was a marked decrease in the number of high temperature bacteria: from 13,600,000 at the end of the fourth run to 348,000 at the end of the fifth. This would seem to indicate that these particular bacteria were not favored by the pasteurization temperature and when the longer period allowed the foam, splash, etc., to attain a higher temperature their numbers were materially reduced. This is in keeping with results obtained by one of us on thermophilic bacteria from this same milk plant at another time. It was found that the bacteria increased rapidly in the foam which was at a lower temperature than the milk, but decreased rapidly in the milk or in foam brought up to the pasteurizing temperature.

What does the thermophilic count indicate? It indicates that one or more of the conditions which we have enumerated exist in the pasteurizing plant. The plant may be receiving unusual contamination; it may be repasteurizing milk brought back from the wagons; the walls of the pasteurizer may have a thin layer of cooked milk in which

thermophiles may grow; the construction of the pasteurizer may be defective so that some of the milk fails to reach the pasteurizing temperature; there may be an excessive amount of foam which is not heated to temperature; or the vats may not be cleaned between runs.

The value of the thermophilic count to the control officer is much the same as the value of the ordinary count. We do not count the bacteria in pasteurized milk because we are especially concerned with the destruction of the particular types of bacteria whose colonies grow on an agar plate. We make these counts because by them we can tell with reasonable certainty whether the milk has been heated to a temperature which will render it free from pathogenic bacteria; whether the plant is operated in a clean and efficient manner; and whether the milk is properly cooled between pasteurization and delivery.

There is no reason to think that the thermophilic bacteria are more harmful in milk than their relatives growing at lower temperatures. In fact since most of them grow very slowly or not at all at low temperatures there is a tendency to regard the thermophilic count as of no significance. Some have even advised to use culture media on which their colonies will not grow and to pretend that they do not exist. This ostrich-like attitude does not appeal to bacteriologists who believe that the plate count should be made to show as correctly and completely as possible the conditions which exist in the milk.

A control officer should welcome a technic which will enable him to detect those pasteurizing plants which are defective and make it possible for milk to leak into the walls of the vat, or which do not heat all of the milk to the required temperature. To be assured that between runs the vats are properly washed and steamed may not be a matter of major importance, but if the omission of this serves to obscure more serious defects it should be corrected.

On the whole we believe that an estimation of the number of thermophiles should be made of real service in the control of pasteurization. However, it is not sufficient to tell a dealer that his milk contains a large number of thermophilic bacteria and that this number must be reduced. Ordinary bacteria are a deep enough mystery for the average milkman. The inspector should be able to point out wherein his methods are defective and how they may be remedied.

Hygiene of the Towel

HERBERT D. PEASE, M. D., F. A. P. H. A., AND LESTER
C. HIMEBAUGH

Pease Laboratories, New York, N. Y.

PUBLIC health authorities have expressed an almost universal desire to banish the common towel. In an effort to develop more concrete evidence that might answer the questions listed in this paper, the authors have made the bacteriological and physical studies described after each. Standard size towels were used in the experiments.

Question 1—When the hands are washed in the usual manner, are bacteria transferred to the towel in appreciable numbers?

The finger tips were inoculated with a 24-hour broth culture of *Flavobacterium lutescens*, a bright yellow chromogenic bacillus. They were held before an electric fan 15 minutes, drying the skin even beyond its normal condition. The hands were then washed with a toilet soap for 10 seconds, rinsed for 5 seconds to remove the soap, and wiped on a sterile Turkish hand towel. After 30 minutes' drying, the towel was examined for the number of bacteria present. Disks 2" in diameter were cut from the center of the towel and one was placed in 100 c.c. of sterile physiological salt solution. Appropriate dilutions were plated in standard beef extract agar and incubated for 2 days at 37° C. when the number of yellow organisms developed from the 2" disk was determined.

A second disk taken from the same towel was placed on a sterile agar surface for 10 seconds. Upon removal, an impression of the towel and some of the bacteria which had been present were left on the plate, which was also incubated for 2 days at 37° C.

In the case of the Turkish hand towel 48,000 bacteria per 2" disk were removed from the finger tips, while the huck towel removed 15,000; so that in common washing practice, not only are large numbers of bacteria apparently transferred to towels, but, comparatively, Turkish towels remove larger quantities than huck.

Question 2—When several individuals use a common towel, may infectious bacteria be transferred from one individual to another?

Three separate investigations were conducted, under both exaggerated and ordinary conditions.

The first series were hand washing tests to show whether bacteria are transferred to subsequent users from original ones.

Individual 1 washed the hands thoroughly with soap and warm water for 1 minute. They were then dried by electric fan. One c.c. of a 24-hour broth culture of *Flavobacterium lutescens* was rubbed over both hands, which were again electrically dried for 15 minutes, and then washed with tap water at about 37° C. and cake toilet soap for 10 seconds; then rinsed for 5 seconds with running tap water and dried thoroughly on a sterile Turkish hand towel. Individual 2 washed his hands thoroughly with soap and warm water for a period of 1 minute, the degree of efficiency of which was determined by finger-printing a nutrient agar plate subsequently incubated at 37° C. for 48 hours. He then dried the hands on the towel which had been used 5 minutes previously by individual 1. After a simple drying of 20 seconds, finger-prints were again taken. The first photograph marked "No. 5 control" (Plate A) indicates a small number of bacteria present after the washing process.

Individual 2 then dried the hands on a towel which had been used 24 hours before by individual 1. After a simple drying of 20 seconds, finger-prints were again taken. The photograph marked "Turkish towel used 24 hours before" shows a much larger number of bacteria than photograph "No. 5 control." Several bright yellow colonies demonstrated a transfer by the towel from individual 1.

Rapid bacterial destruction through desiccation in the absence of nutrient material has been generally postulated. The results of tests by individual 2 after both 5- and 24-hour intervals were somewhat similar to those obtained after the 5-minute interval and indicated duration of viability of bacteria on the towel contamination by individual 1. Small numbers of bacteria died by reason of the longer periods of sojourn on the towel, but a major number remained, ready to contaminate the hands of anyone using the towel the second time.

To compare the action of huck hand towels, this entire series of tests with Turkish hand towels was repeated, using huck towels. A slightly greater number of bacteria were transferred to the hands at the end of the 5- and 24-hour periods (Plate A). This was confirmed in several tests and indicates readier pick-up of bacteria from the flat surfaces of the huck towel than from the rough surface of the Turkish hand towel.

The second series of studies comprised hand washing tests to demonstrate whether or not multiple infections can be transferred to each user of the common towel; i.e., to indicate what is apt to occur when a towel is infected by several people.

PLATE A

IMPRESSION INOCULATIONS ON AGAR BY FINGER TIPS AFTER WASHING AND RINSING, THEN DRYING ON USED TURKISH HAND TOWEL AND ON USED HUCK TOWEL

1—No. 5 Control, Washed Hands

2—No. 5 Turkish Towel Used 24 Hours Before

3—No. 6 Control, Washed Hands

4—No. 6 Huck Towel Used 24 Hours Before

In this series of studies four individuals participated, employing the same technic. Individual 1 washed his hands thoroughly with soap and warm water for 1 minute, afterward drying them for 15 minutes. One c.c. of a 24-hour broth culture of the bright yellow chromogen *Flavobacterium lutescens* was rubbed over the hands, which were dried as before, then washed with tap water at approximately 37° C. and cake toilet soap for 10 seconds. The hands were then rinsed for 5 seconds and dried on a sterile Turkish hand towel.

Individual 2 repeated the same process with hands inoculated with 1 c.c. of a 48-hour broth culture of the easily distinguishable, red *B. prodigiosus*. Finger-prints on agar plates were made after wiping the hands on the towel infected by individual 1. The plates were incubated for 48 hours at 30° C., when they showed many bright yellow colonies and a still larger number of red colonies, indicating infection of the hands of individual 2 by the organism left on the towel by individual 1.

Individual 3 repeated the same process with hands inoculated with 1 c.c. of a 24-hour broth culture of the light orange *M. aureus*, to distinguish this organism from those used in inoculating the hands of individuals 1 and 2. Finger-prints on agar plates were made after wiping the hands on the towel previously used by individuals 1 and 2. The plates were incubated for 48 hours at 30° C. They showed many bright yellow and red colonies and a still larger number of light orange colonies, indicating that individual 3 had become infected by the organisms left on the towel by individuals 1 and 2.

Individual 4, after thoroughly washing the hands, employed the towel previously used by individuals 1, 2, and 3. After the usual wiping process, finger-prints were made as before. The plates showed the presence of all three organisms, indicating that the hands of individual 4 had become infected with all three organisms left on the towel by the three previous users.

A huck hand towel was used in a further series of tests. The results were identical, except the numbers of bacteria transferred to individuals 2, 3, and 4 were greater.

It was thus clearly indicated that infectious bacteria may be easily transferred in increasing varieties and numbers through the use of the common towel, especially by the huck hand variety.

The next series of studies considered the accumulation of bacteria on the towel when used by different individuals and whether the varieties of bacteria increased when the towel was used by them. Turkish and huck hand towels were used on four occasions by four different individuals as previously described. Imprints were made after one individual had used the towel and again after four had used it, when it was observed to carry decidedly increased numbers of bacteria.

A further series of tests was conducted to show whether an increase in the varieties as well as numbers of bacteria would occur. When one person used the Turkish towel, an average of over ten types of bacteria was found. The same towel after use by four individuals showed an average of over twenty types of bacteria.

The organisms used in the studies thus far, with the exception of *Micrococcus aureus*, would be classifiable as non-pathogenic.

Many have believed that pathogenic bacteria die rapidly through desiccation, even in the absence of sunlight. If infectious organisms such as might find their way to the common towel were capable of remaining alive over periods of 24 or 48 hours, a real danger would be indicated when the ease of transfer as shown in the previous results is considered.

The next series of studies was conducted to determine whether various species of pathogenic organisms would remain alive for periods of 24 and 48 hours. Sterile disks 2" in diameter were inoculated with cultures of the following infectious organisms: *Bacillus typhosus*, *Bacillus paratyphosus* "B," *Bacillus diphtheriae*, *Streptococcus hemolyticus scarlatinae*, *Streptococcus hemolyticus*, *Pneumococcus Type II*. In each case the organisms were grown on a suitable solid culture medium and, to avoid carrying over to the towel any culture medium which might aid the organism in remaining alive, only the surface growth was used. After inoculation, the disks were placed in clay-top Petri dishes at room temperature and subjected only to a north light. At intervals of 24 and 48 hours, disks of each type of towelling were removed and small portions transferred to suitable culture media. After incubation for 48 to 72 hours, macroscopic and microscopic examinations were made.

TABLE I

VIABILITY OF PATHOGENIC MICROÖRGANISMS ON DRY TOWELLING
(In absence of direct sunlight)

Test Organisms	Alive at end of

<i>Streptococcus hemolyticus</i>	+	+	+	—
<i>Pneumococcus Type II</i>	+	+	—	—

Living infectious organisms of all these varieties were present on both Turkish and huck hand towels for a period of 24 hours. No pneumococcus survived for 48 hours. *Streptococcus hemolyticus* may or may not die under these conditions within 48 hours. Apparently, therefore, real dangers from infectious organisms exist in the common towel for at least 48 hours after primary contamination.

Question 3—Will the repeated use for several days by one individual show an accumulation of bacteria on the towel?—what is the sanitary significance of such accumulations?

Studies were conducted to bring out the possible accumulation of

bacteria during the normal home use of the large Turkish towel upon the entire body; the small Turkish towel upon the hands and face; and the huck towel upon the hands and face. Four individuals participated in each of the three series.

LARGE TURKISH TOWELS

Twenty-four large Turkish towels were washed, wrapped separately in paper and sterilized in an autoclave. Six of these prepared towels were given to each of four persons, one of which was used but once to dry the entire surface of the body and was returned to its wrapper and the laboratory for testing. The second was used in the same way on each of 2 consecutive days and then wrapped and returned. The third was likewise employed on each of 3 consecutive days and the fourth, fifth and sixth towels were similarly used on 4, 5 and 6 consecutive days respectively. Between times they hung on the bathroom towel racks under normal home conditions. After each period, determinations were made in the laboratory of the accumulated numbers of bacteria on the towels during the several periods covered. Four 2" disks were removed from different parts of the towels. Three disks were placed in 100 c.c. of sterile physiological salt solution and appropriate dilutions were plated separately in standard beef extract broth. The average of the results for the three disks was taken as the bacterial count for each towel used for the given time period. The results appear in Table II.

TABLE II

BACTERIAL COUNTS FROM TWO-INCH DISKS TAKEN FROM LARGE TURKISH TOWELS USED BY ONE INDIVIDUAL ONE BATH A DAY—FOR PERIODS OF ONE TO SIX DAYS

Number of Days Towel Was Used	Individual 1	Individual 2	Individual 3	Individual 4
1	26,500	38,000	700	4,500
2	17,500	180,000	4,700	18,000
3	46,500	110,000	16,000	9,600
4	100,000	410,000	38,000	43,000
5	100,000	300,000	203,000	81,000
6	240,000	310,000	800,000	178,000

The remaining disk from each of the towels was imprinted on a nutrient agar plate to indicate the distribution of the bacteria on the disk and their increase in numbers. The plates were incubated at 37° C. for 48 hours, and one set including the control was photographed (Plate B).

In each case the imprints indicated a decided increase in the number of bacteria. In the photographs the loose threads or portions of threads may be distinguished readily from the colonies of bacteria.

The results indicate clearly that when a bath towel is used more

PLATE B

1—*Turkish Towel Before Using*2—*Large Turkish Towel Used Once*3—*Large Turkish Towel Used 3 Times*4—*Large Turkish Towel Used 6 Times*

than once bacteria accumulate on it. Variations in results from the towels used by different individuals were remarkably small.

TURKISH HAND TOWELS

A similar series of tests was conducted by four individuals using a small Turkish hand towel, morning and night, to dry the face and hands, during each of six periods, each period ranging from 1 to 6 days. The results appear in Table III.

The agar plate impressions of the 2" disks taken from the towel used by the four individuals showed approximately the same graphic

TABLE III

AVERAGE BACTERIAL COUNTS ON TWO-INCH DISKS TAKEN FROM TURKISH HAND TOWELS EACH USED BY ONE INDIVIDUAL—MORNING AND NIGHT—FOR A PERIOD OF 1 TO 6 DAYS

Number of Days Towel Was Used	Individual 1		Individual 2		Individual 3		Individual 4	
	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts
1	3	3,800	5	25,500	4	11,500	5	20,500
2	6	9,000	10	55,000	8	9,900	8	48,000
3	10	17,800	15	54,000	12	16,000	13	57,000
4	15	83,000	20	140,000	18	84,000	18	113,000
5	17	70,000	25	143,000	22	180,000	24	95,000
6	20	174,000	30	294,000	28	210,000	30	133,000

results as those obtained in the tests with the Turkish bath towel. The numbers of bacteria were not quite so great but clearly indicated the accumulation and survival of bacteria during different periods of use. Again there were remarkably small variations between individuals for the various time periods.

HUCK HAND TOWELS

Another series of tests was conducted exactly as those previously described for the Turkish hand towels. The results are given in Table IV.

TABLE IV

BACTERIAL COUNTS ON TWO-INCH DISKS TAKEN FROM HUCK HAND TOWELS EACH USED BY ONE INDIVIDUAL—MORNING AND NIGHT—FOR A PERIOD OF 1 TO 6 DAYS

Number of Days Towel Was Used	Individual 1		Individual 2		Individual 3		Individual 4	
	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts	Number of times used	Bacterial Counts
1	2	12,500	6	25,500	5	12,500	6	11,000
2	6	27,000	12	60,000	6	48,500	9	18,500
3	9	38,500	15	75,000	9	38,500	16	14,500
4	16	52,000	20	44,500	21	13,000	18	38,000
5	15	44,000	25	150,000	22	56,000	21	6,800
6	17	96,500	30	180,000	24	54,500	28	15,000

Substantially the same photographic results were obtained from disk tests as in the two preceding studies (Plate C). A comparison of photographs of the huck with those of the small Turkish towel indicated a larger number of organisms in the case of the former. For comparison, averages of the results obtained on the three types of towels by each of the four individuals are given in Table V, which indicates that larger numbers of bacteria were removed and accumulated by both types of Turkish towelling than by the huck towelling.

The results of these tests decisively show the accumulation of bacteria on a towel used more than once by even one individual. If the

PLATE C

IMPRESSION INOCULATIONS ON AGAR BY DISKS CUT FROM HUCK HAND TOWEL

1—Huck Towel, Before Using

2—Huck Towel, Used 1 Day

3—Huck Towel, Used 3 Days

4—Huck Towel, Used 6 Days

same towel were used by several, similar results should be obtained.

Considering the sanitary significances of such accumulations of bacteria, the results obtained in answering *Question 2* indicate that the individual who uses the same towel on the face, hands or body more than once will not only remove a considerable number of bacteria from the skin but will simultaneously become re-inoculated with the bacteria which he left on the towel previously. The dangers of this practice might be illustrated by an individual who with hands which had become accidentally contaminated with typhoid bacilli washes them ineffectively and dries them on the towel. With the

TABLE V

AVERAGE BACTERIAL COUNTS ON TWO-INCH DISKS TAKEN FROM TURKISH BATH TOWELS, TURKISH HAND TOWELS, AND HUCK HAND TOWELS

Number of Days Towels Were Used	Turkish Bath Towel	Turkish Hand Towel	Huck Hand Towel
1	17,400	15,200	15,300
2	54,500	30,400	36,000
3	70,000	36,400	42,800
4	148,000	105,000	36,500
5	171,000	122,000	64,200
6	382,000	202,000	61,500

next use of the towel, perhaps hours or days later, the hands would re-acquire some of the bacilli which had been previously transferred to the towel and the possibility of infection of food or anything entering the mouth would be substantially as great as at the time of the original contaminations. The numbers of typhoid bacilli would likely be smaller but the opportunity for infection would remain.

In view of these studies, the use of the individual towel more than once must be considered as potentially menacing, and its repeated use, especially over periods of days, should be avoided.

Question 4—Which of the three types of towels—Turkish, huck, and paper—will prove most efficient in the removal of bacteria from the skin?

The results of the foregoing studies have clearly shown the towel as an important factor in removing bacteria from the skin. The selection of the type of towel capable of removing the largest numbers of organisms from the skin therefore becomes important as a sanitary measure. To this end, determinations were made of the numbers of bacteria remaining on the skin after the use of Turkish, huck, and paper types of hand towelling.

The technic employed was identical with that in the first series of tests to answer *Question 2*. Four individuals participated. Finger-prints before washing showed substantial numbers of organisms and photographs of such control finger-prints show the results from the unwashed hands. During the actual testing, no finger-prints of the unwashed hands could be made, as this would have removed sufficient numbers of bacteria to vitiate the results (Plate D).

After washing the hands, each individual used a Turkish hand towel, the huck, and the paper hand towel in successive tests. When the hands were dried, imprints on agar plates were made and the latter incubated for 48 hours at 37° C.

Photographs of the finger-prints of one individual demonstrate the differences found. These are representative of the results obtained from the tests on all four individuals. They indicate that smaller

PLATE D

Huck Towel Used4—Inoculated Hands, After Washing.
Paper Towel Used

numbers of bacteria remained on the hands when using the Turkish hand towel than with the huck hand towel. Substantiating the previous studies, the largest number of organisms remained on the hands when the paper towel was used, which was to have been expected, since one usually blots with a paper towel rather than rubs the skin dry (Plate D). A definite guide is thus afforded indicating the Turkish towel as more efficient with one using than either the huck or the paper towel. The paper towel is employed but once, the others should be used but once also.

Question 5—Which of the three types of towels—Turkish, huck, or paper—will be most efficient in removing visible dirt from the skin?

From observation and comparison of the three types of towelling, the Turkish, having a loose, flexible thread with a rough yet pliable exterior and therefore an increased surface for contact with the skin, should be able to remove from the uneven surface of the hands a larger amount of visible dirt than the huck, and still more than the paper towel. To help demonstrate the difference between the action of the several types of towelling, exaggerated conditions of dirty skin were produced in the first of a series of tests by rubbing, with a little water, 0.1 gm. of lamp black onto the hands. After it had dried for 15 minutes, they were washed as usual for 10 seconds with cake soap and water. After rinsing for 5 seconds they were dried on the Turkish hand towel. Observations of hands and towel were recorded. The day following, the same tests were made by four individuals using the huck hand towel and repeated the next day using paper towels.

The superiority of the Turkish type of towel was again evidenced since larger amounts of lamp black were retained by it than by the huck and much more than by the paper towel, while the skin of the Turkish towel user was cleaner than that of those who used either of the others.

Because so substantial an amount of lamp black had been used in the first tests, they were repeated with as small quantities of lamp black as 0.01 and 0.002 gm. Little difference could be observed in the appearance of the towels as between the Turkish and huck varieties, but again the hands of each individual were cleaner where the Turkish type had been employed. Although crude, this series of tests demonstrates that the Turkish hand towel is superior to the huck or paper type in removing foreign matter from the skin. Single service hand towels, preferably of the Turkish type, give the cleanest appearing hands.

SUMMARY

The results of the investigation show some of the effects of the use or misuse of towels and the important part towels may play in the spread of bacteria which may be of disease producing types.

Although public health officials have recognized that the skin, especially that of the hands, may be one of the most important modes of transfer of disease producing organisms, and that diseases other than those of known bacterial origin may also be readily carried by the same means, the part played by the misuse of towels and the relative merits of types of towels have not received so much attention. Tests to secure evidence regarding these points indicate that:

Bacteria are transferred from the hands to the towel in surprisingly large numbers.

Bacteria are readily transferred from one user to another through the medium of the towel.

Most of the common disease producing bacteria, even though in a dry state, may remain alive on the towel for at least 24 hours and generally longer, making the common towel a constant and continued source of danger.

When the towel is used repeatedly by the same individual the numbers of bacteria on and in it are increased and some of these in turn may be restored to the hands of the user. Potential danger exists of a possible re-infection of the hands with disease producing organisms left on the towel by prior use. Repeated drying with an individual towel is not a good sanitary practice.

The Turkish towel, owing to its construction and a consequently greater number of points of contact with the skin, removes greater numbers of bacteria and dirt particles from the skin than the huck towel or the paper towel.

CONCLUSIONS

The common towel in public or in the home is an ever present menace as a potential carrier of disease producing organisms which thus may be easily transferred to the hands of each new user.

Whether for drying the face, hands, or entire body, the employment of an individual single service towel constitutes a wise precaution against excessive numbers of relatively harmless or of disease producing contaminations by bacteria already on previously used towels.

The Turkish towel is more efficient than the huck or the paper towel in removing bacteria and dirt from the skin.

Most Automobile Accidents Due to Law Violation

CAREFULLY compiled statistics in California show that traffic laws have been violated in connection with 60 per cent of the fatal automobile accidents in that state and that inexperienced drivers are involved in about 80 per cent of all fatal motor mishaps. These facts give a very practicable basis for launching a definite campaign against highway accidents that offers hope for a long time overdue improvement in the accident rate.

In California a system of recording accidents and law violations has been adopted. This includes the name of the drivers involved. When three charges are found against the same individual within a 6-months period, the individual is required to undergo a special examination to determine his competency as a driver. In view of the statistical evidence cited above the California system, if prosecuted vigorously, ought to bring about a significant improvement in the automobile accident situation.

Problems in Public Health Administration*

GEORGE C. RUHLAND, M. D., F. A. P. H. A.

Health Commissioner, Syracuse, N. Y.

TO casual observation, the creation of a special section for health officers in the American Public Health Association must seem somewhat unusual, in view of the fact that this Association was conceived and brought into being primarily by and for health officers. However, a moment's reflection will make clear that this apparently paradoxical situation is after all a very natural outcome of growth and progress. With the development of the various special activities that have been adopted into standard modern health department practice, it was inevitable that these various specialties would seek and secure a separate place in the organization where their particular problems could be discussed by fellow craftsmen.

After all, though the members of this Association are all devoted to the same general interest—that of promoting the public health—the particular interests of the various groups are not quite the same, nor do they even speak the same technical language. Separation into groups of specialties was therefore unavoidable, and also desirable for the development of the Association and the advancement of its work.

In the evolution of modern public health service, the health officer finds himself little by little further separated from activities which he formerly undertook personally. Gradually he ceases to be diagnostician, registrar of vital statistics, quarantine officer, milk inspector, and sanitary police officer all in one. The fact is that the general practitioner in public health, as in the practice of medicine, is rapidly going out of fashion; and in his place a new type of health officer appears—one who no longer attempts to be a clinician, sanitary inspector, etc., but who, in conformity with the demands of a larger and modernized service, is first and foremost an organizer and administrator.

This does not mean that the health officer surrenders his interest in any one of the various activities represented in modern health work. On the contrary, he must have intimate knowledge of all these matters

* Read before the Health Officers Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 1, 1929.

in order that he may properly evaluate their importance and competently direct the development of the service of which he is the responsible chief.

However, what must be realized and understood is that public health, fortunately, is emerging out of the one-man type of service and in place thereof service through organization or group practice has come into being. Just as in the practice of medicine we have come to appreciate that no one man can hope to be fully familiar and equally efficient in all the various specialties into which medical knowledge has extended, so too in the various activities of public health no one man can expect to be equally competent, even if he were physically able to undertake all of the work required in modern service. Public health therefore functions through specialists in its various activities.

Although a number of health departments for many years have been organized and functioning under this enlarged and modern service plan, it would appear from the papers annually read by the health officers at the meetings of this Association that they have not yet awakened to the fact that their service has changed, and their relationship to that service calls for a consideration of new and special problems that are peculiarly and specifically their responsibility.

Why should the health officer undertake to present papers on problems in epidemiology, vital statistics, and child welfare, or any one of the specialties, when he has in his organization those who are presumably expert in these matters and who can handle these subjects with at least equal competency? The explanation is, of course, that we have not apparently realized that we have new and very important responsibilities as administrators, and are still following the traditional practice of the past.

It is most stimulating and promising to find a special place given in the present program at which health officers are to discuss problems that are essentially of an administrative nature.

In a general way, the special responsibilities of the health officer may be classified under four major groupings:

1. Those that have to do immediately with the organization and management of the service as a department activity.
2. Those that deal with the department in its relation to other branches of government.
3. Those that establish coöperation and deal with voluntary health agencies.
4. Those that affect the relationship of the public in general and its special organized groups such as the medical societies, parent-teacher associations, etc.

It is obviously beyond the scope of this paper to discuss every one of these service relationships even superficially. I propose to deal

only with the first group of administrative problems in the above list—those that deal with what may be called “internal affairs,” and with only a few of these.

This Association, through its Committee on Administrative Practice, has furnished the health officer in the *Appraisal Form* a valuable guide for the development of his service.

Bulletin 164, on Municipal Health Department Practice, published by the U. S. Public Health Service, *Community Health Organization*, edited by Professor Hiscock, and the record forms for municipal public health service worked out by another committee of this Association are, of course, familiar to you as useful references and aids in the organization and development of service. However, organization and service depend ultimately on the human equation, and propose such problems as competent and qualified workers, hours of service, compensation, sick leave, disciplinary action, housing, budgets, etc.

What is the practice and experience of health officers in building up and maintaining competent and smoothly functioning health machinery? In order to obtain information on this point, a questionnaire was sent last summer (1929) to health officers of various cities having a population of 200,000 or more. To get as comprehensive a picture as possible, the cities were selected so that every section of the country would be represented.*

The 8-hour day seems to be favored for health department service: 11 out of the 22 cities require that number of hours, 7 only 7 hours, and 2 require 7½ and 8½ hours respectively. Medical service is essentially on a part-time basis, 18 cities reporting it on that basis.

The question dealing with the procedure to determine the qualification and fitness of the applicant for service was answered by 18 of the cities as follows: in 6 the health officer decides; in 1 the health officer passes on physicians and nurses only and the civil service board on all others; in the majority, 10, the matter is handled by civil service; and in 1 city the health officer “suggests qualifications to the civil service board.”

The matter of physical fitness of the applicant appears still very unsatisfactory, and this is rather disappointing in view of the fact that health departments are preaching periodic health examinations as an important factor toward health and efficiency. Of the 19 cities which replied to the question, 12 required no such examination; 5 required it, and 2 required examinations for nurses only. In 3 cities the physical examinations are undertaken by the civil service board; in 2 by

* Answers were received from 22 cities: Atlanta, Baltimore, Buffalo, Chicago, Cleveland, Cincinnati, Denver, Detroit, Kansas City, Los Angeles, Louisville, Nashville, New Haven, Newark, New York, Milwaukee, Minneapolis, Portland, St. Louis, San Antonio, San Francisco and Seattle.

the health department, and in 1 of these at the request of the civil service board. In 1 other the health officer is the examining physician.

The question obviously arises—Should not health departments practice what they preach? Should they not prevail upon civil service to make physical competence a fundamental requirement and so protect the public service, and also help the individual to learn of physical handicaps and assist in their correction? Manifestly an examination cannot fully determine the applicant's fitness for service. Time alone will tell.

Twenty-one replies were received to the question—Is there a probationary period, and if so, how long? One city allows a 30-day period; another 2 months; 5 place the period at 3 months. Six months is the time fixed for nurses only in 1 city. Eight others require a 6-month probationary period for all health department employees, and 5 require no probation.

The question as to disciplinary control was answered by 19 of the 22 departments replying. Seven stated that suspension from service was discretionary with the health officer; 3 that it may be undertaken through civil service only. In 1 this authority is entirely in the hands of a board of public safety, while in 3, such disciplinary measures are frankly political, since in 1 this action rests with the mayor and in 2 the city council handles the matter.

Unless suspension carries with it monetary loss, or repetition automatically leads to discharge, it is a meaningless procedure and equivalent to a vacation with pay. In 1 city suspension for 90 days without pay is permissible, in 4 others it is practiced for a period not to exceed 30 days.

Practice with regard to complete and permanent separation from service brought answers from 12 departments. Six stated that action for discharge from service was effected through civil service; 2 did so through the board of public welfare or public safety, of which the health department is a part; in 3 this authority is in the hands of the health officer; and in 1 it rests with the mayor. Appeal from a discharge action was reported in 6 cities through civil service; 1 dealt with it through the mayor; and 1 through common council. One health officer reports that appeal is provided for veterans only.

While management unquestionably succeeds best when it secures the whole hearted and good will coöperation of employees, manifestly insubordination, laziness, disinterest and inefficiency cannot be tolerated. The authority of the department and bureau chiefs must be respected. If minor infractions of discipline cannot be adjusted by

the bureau chief, the department should have authority to suspend without pay for a limited period of time. Repetition of the offense should lead to dismissal through the civil service.

The question of vacation is important, since it involves curtailment in service. Obviously the time for vacations should be so adjusted that the service will suffer least. All but one of the 22 cities replying stated that the authority to fix the time for vacations rests with the health officer. The length of vacation varies from 12 days for clerks and inspectors to 24 for the technical and professional groups. Twelve answers stated that holidays are included in the time allowed; and 10 that they are not.

The practice of granting vacation to employees who have been in service for less than 1 year varies considerably. In 8 cities no vacation is granted to such employees; 2 grant them but do not give the detail of practice. In 1 the health officer decides; in others an allowance of from 1 to 2 days per month of service is made.

Sick leave with pay is not granted in 2 of the 22 cities; 1 allows 30 days; 1, 29 days; 2 others, 10 and 15 respectively; 4, 14 days; 2 state it as "two weeks"; one, "1 week per year of service"; 3 say "conditional," without stating what these conditions are. One allows 75 per cent of the salary for 12 days and 50 per cent for 24 days; another leaves the matter to the discretion of the health officer.

In 14 of the cities, employees are eligible to compensation insurance if injured in line of duty; 7 have no such provision; and 1 did not answer.

Old age retirement is provided for by 11 cities only. The age limit varies from 60 to 70 years, with qualifications in some. Three permit retirement after 25 years of service, while only 4 stated that a pension was given.

The matter of adequate compensation is always an important one, since it is the means of securing and holding competent service. Shall the health officer have a voice in determining what the compensation in his department shall be? Answers were received from 19 health officers. It appears that in the majority of instances the health officer is consulted about the salaries. In 8 cities this matter is in the hands of the health officer, but no details were given. In 7 departments out of 20, salaries are on a graded scale. In 1 city only the salaries paid to nurses and inspectors are graded. The practice in the remaining 12 leaves the matter of increase to the mayor, the council or special boards, and 1 to "pull."

Manifestly the various points mentioned so far by no means represent the sum total of administrative problems, even in so far only as

these have to do with the internal affairs of the department. Organization, housing, budgets, service routine—especially as this has to do with requisitions for supplies and equipment—staff conferences, etc., are all important matters. Then, as already mentioned, there are the special problems that have to do with the department's relationship to government, to volunteer health agencies, the medical profession, and the public in general.

What has been presented must make it clear that there exists considerable diversity of practice and that there is quite definitely room for improvement.

No attempt has been made here to lay down categorically rules for administrative procedure. There is no doubt, however, that further study of administration methods now in practice will prove useful for the improvement of departmental efficiency, and helpful to the administrator in discharge of his duties.

Public health administration is a specialty which, if it is to take and maintain its position along with other public services, must adopt modern methods of business.

The Teaching of Bacteriology and Public Health to Hospital Nurses

HOSPITAL nurses should come to graduation with a practical knowledge of bacteriology, epidemiology and public health. Too often their instructors are technicians or members of the hospital staff years removed from the subject, or staff nurses selected because of their inadaptability for other duties. It is perfectly true that prescribed courses are mentioned in the curriculum for hospital nurses but it is not infrequent that the course in bacteriology, at least, is given without the student obtaining actual laboratory experience.

It is likewise true that hospital nurses are not intended to be bacteriologists but their varied duties are such that sterile technic at the bedside and in the operating room is dependent upon existing bacteriologic flora and a workable knowledge of the reasons for possible contamination and the contaminants is necessary. Just as necessary are the fundamentals of the epidemiology and public health measures to be used to combat disease.

The nurse is quite frequently the confidante and companion of the patient and the understanding of questions with their proper answers is equally as important as is sympathy and bedside care. Superintendents of hospitals should carefully scrutinize such instruction in order that the graduate nurse will have some adequate familiarity with laboratory technic and public health procedures.—J. C. Geiger, University of California.

Report of Visits to Local Registrars of Vital Statistics in Maryland*

JOHN COLLINSON, M. D., DR. P. H., F. A. P. H. A.

Chief, Bureau of Vital Statistics, State Department of Health, Baltimore, Md.

THE system of registration of births and deaths operating in Maryland is that recommended by the U. S. Bureau of the Census. This was adopted in 1912, and is as follows:

The 23 counties of the state, having a population of 800,000 and an area of 9,933 square miles, are divided into 201 registration districts with a local and deputy local registrar in each. These are held responsible for the complete and accurate registration of births and deaths in their respective districts. Their detailed duties are to receive original birth and death certificates, issue burial and transportation permits, keep records of all certificates received and permits issued, and to acknowledge receipt of birth certificates on post cards supplied. Before the 5th of each month the local registrars forward to the state registrar all original certificates of birth and death which they and their deputies have received during the previous month. For these services the county pays the registrar 35 cents for each original certificate recorded. Applicants pay 25 cents each for burial permits issued upon transit permits, and for disinterment permits issued to them.

The City of Baltimore, which includes approximately half the population of Maryland, comprises one registration district. The registration and preservation of certificates in this district are under the direction of the Health Commissioner of the city. This discussion, therefore, does not include Baltimore.

For the purpose of becoming personally acquainted with the registrars and their work, and of arousing their interest in the activities of the Bureau of Vital Statistics, 121 local registrars, whose districts are scattered generally over the state, were visited during the period April 1 to September 15, of this year. Each was closely and systematically questioned and notes were made regarding

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

1. His profession
2. His familiarity with the duties of his position
3. Whether the necessary office records were being kept
4. The difficulties experienced in obtaining complete reports from physicians, midwives, undertakers, and sextons respectively
5. Checks used to determine the completeness of registration in his district

The summary of findings is as follows:

1. Those who have some clerical work as their regular duty, such as bank clerks, postmasters, and store keepers, make the best registrars. Farmers, physicians, and undertakers are, as a rule, undesirable. An old resident, familiar with the district and its people, is usually preferred to one who has recently settled in the community.

2. Registrars were found to have a working knowledge of the law pertaining to their duties, except that section concerning the issuing of burial permits on presentation of the transit permits which usually accompany bodies brought into Maryland.

3. Office records of birth and death certificates received and of burial permits issued were found to be complete and neatly recorded.

4. In the opinion of registrars, physicians are more negligent in reporting births than licensed midwives. Unlicensed midwives frequently do not report in order to escape prosecution for practicing. It was stated that some undertakers obtain burial permits from the most conveniently located registrars, instead of from the registrar of the district in which the death occurred. The Maryland law states that sextons shall return all burial permits to the local registrar of the district in which the burial takes place. This is not strictly complied with.

5. Probably the most important part of the inquiry was that dealing with the checks used by registrars and efforts made to insure complete registration of births, deaths and burials.

Registrars of small rural communities stated with assurance that they hear through neighborhood gossip of all births which occur in their districts. Registrars of towns of 5,000 and over do not hear of all births and know of no practical way of determining the completeness of registration. Settlements of negroes and communities of foreigners add to the difficulties of local registrars, as in these groups a member of the family who does not know the importance of reporting frequently officiates at the birth.

A few registrars telephone physicians each month, asking that all births attended be reported. Some periodically make the same inquiry of midwives, but these are the exception. All report violations or suspected violations of the law to the State Registrar, if they are known to have occurred and cannot be corrected locally.

The occurrence of a death even in a large community is heard of by the registrar, and the penalty for not properly recording it is generally understood.

The law requiring the return of burial permits to local registrars

does not operate as a satisfactory check on interments, as frequently sextons neglect this duty, and many farms have private cemeteries with no person in active charge.

In conclusion, as recent visits to local registrars have promoted better coöperation and understanding, it is believed that the central office and local health officers should always keep in close touch with representatives in the districts by frequent visits and correspondence.

The present system of the collection of vital statistics in Maryland is operating satisfactorily. It is inferred from reports that death certificates are received and burial permits issued for more than 99 per cent of the deaths which occur, stillbirths excepted.

Taking the state as a whole, Baltimore City excluded, the registration of births was 96.1 per cent complete in 1928, as judged by checking certificates of deaths of infants who died under 1 year against birth certificates to determine if the birth had been reported. There are districts, however, in which there is more than a suspicion that birth reporting is deficient. The evidence collected would indicate that local registrars can do little more to remedy the matter than they are now doing. They consider their position an honor, the duties of their office a serious responsibility, and demand compliance with the law. Success in obtaining complete registration of births and deaths, therefore, as in other fields of public health, must depend on our ability to convince the public of its necessity and value.

DISCUSSION

W. THURBER FALES, F. A. P. H. A.

*State Registrar, Bureau of Vital Statistics, State Board of Health,
Montgomery, Ala.*

THE conditions in Maryland are very similar to those in Alabama. There are, of course, differences as to details, but the problems for the most part are the same.

During the past three summers Alabama has had three or four students, usually medical, doing field work in vital statistics. They have visited registrars, undertakers, coffin dealers and doctors. The following facts were found, and comparison with the findings of Dr. Collinson is interesting:

1. Of the 159 registrars visited this summer, 61 per cent were men and 39 per cent women—33 per cent were farmers, 28 per cent housewives and 39 per cent had other occupations. We have also found that clerical workers make perhaps the best registrars and for this reason have linked up registration with justices of the peace in the various sub-divisions of the county with good results.

2. This is the first definite field work among registrars carried out, and we

found that many registrars as well as undertakers and coffin dealers sadly needed the instruction made possible by these field visits.

3. We found that the registrars were keeping very accurate and complete records of the births and deaths passing through their hands, 95 per cent of them keeping them as required by law. The question of returning the burial permit to the local registrar has been a difficult one in Alabama. The sextons, with the exception of those in cemeteries located in the towns—and not even in all of these—do not carry out this part of the law. As a result our circuit is not entirely closed and I regret to say that for probably not more than 75 per cent of all deaths in the state are burial permits actually secured before burial.

TABULATION OF VISITS TO ALABAMA REGISTRARS BY FIELD MEN

No. Registrars visited	159
No. Counties included in these visits	14
Average no. days spent in these counties *	10
Time of visits	June 1 to Sept. 15, 1929

	No.	Per cent
Men registrars	97	61
Women registrars	62	39
Registrars who are farmers	53	33
Registrars who are housewives	45	28
Those of other occupations	61	39
Registrars having deputies	83	52
Registrars with registry of midwives	91	57
Registrars keeping record of births and deaths	152	95
Registrars issuing permits before burial	75	45
Registrars sending in properly filled out certificates	122	76
Registrars sending in confidential reports	62	39
Registrars having more than one beat	26	16

* Includes time spent in visits to all coffin dealers, undertakers and doctors in counties.

Infant Mortality in Latin America

IN the registration area of the United States, the infant mortality rate was 65 in 1927 whereas in the countries of Latin America the lowest rate is about 110; between 110 and 115 in Uruguay and between 110 and 112 in Argentina. In other parts of Latin America it is much higher. For instance, in Brazil, where infant mortality figures are available for some cities, only 2 in the last few years showed an infant mortality rate of 150 to 170; and in Porto Alegre the rate was 292 in 1925.

The medical and social causes of infant mortality are discussed, and the need of a central government agency for maternity and child welfare is emphasized. References are frequently made to conditions in the United States.—*La Mortalidad Infantil en Algunos Países de la América del Sur*, by Dr. Gregoric Aráoz Alfaro, honorary professor of medicine at the University of Buenos Aires and former president of the National Department of Health of Argentina, *Boletín de la Unión Pan-americana*, Washington, May, 1930, pp. 505–523.

Elusive Features in the Epidemiology of the Common Cold *

WADE H. FROST, M. D., F. A. P. H. A.

School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

THE common cold is of such frequent occurrence that our opportunities for observing it would seem to be unlimited; yet we have accumulated exceedingly little exact knowledge and less understanding of its epidemiology. We know, in a general way, that it is of world-wide and common occurrence; but we have very scant records of its actual prevalence and distribution in the different elements of any population, still less of its relative prevalence in different parts of the world and in different periods of time.

As to etiology, it is generally believed that the malady is an infection, directly transmissible from person to person, and that certain special circumstances, such as chilling and fatigue, are contributory factors of some importance. These beliefs, however, are based largely upon impressions or so-called common knowledge; they are held somewhat tentatively; and are rather vaguely defined with respect to the nature of the infection—whether it be specific or heterogeneous, primary or secondary—and in the relative importance attached to supposed contributory causes.

In explanation of this backward state of knowledge, there are several features of the common cold which tend to make the collection and interpretation of significant epidemiological data unusually difficult. In the first place, the disease is of such trivial character that, until recent years, it has attracted little serious study except from the angle of bacteriology. Also, because of this triviality, exact records of its prevalence, distribution and clinical course are not obtainable except by elaborate arrangements for special observation of selected groups. Again, the high prevalence of the disease, together with the fact that it causes such slight disability, makes it exceedingly difficult to obtain reliable accounts of the contact relations between cases and even more difficult to interpret such records after they have been collected.

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

Then too, the fact that colds usually recur in the same person at intervals of a few months necessitates keeping the same individuals under continuous observation for rather long periods; and moreover, whatever interpretation be placed upon this tendency to recurrence, it implies complexities of epidemiology. However, the most baffling features of the disease are (1) that it lacks sharp clinical definition, and (2) that experimental research has yielded only indecisive results.

Referring first to bacteriological and other experimental investigations, they have been so extensive and varied that many different shadings of interpretation may be given to the findings. It is, however, a reasonably fair summary to say that the results to date leave it in doubt whether the pathological reaction which we call a cold is caused by (1) a specific infection, the same in all cases; (2) infection by any one of various organisms; or (3) some non-infectious process which opens the way for bacterial invasion as a secondary phenomenon. If any more definite general result may be claimed, it is, perhaps, that the trend of recent work has been to strengthen the evidence in favor of infection as the primary process; to indicate that none of the easily cultivated organisms commonly found in the respiratory passages bears a specific relation to the disease; and to point toward a filter-passing organism or group of organisms as the primary and essential cause. These, however, are only suggestive indications, not established conclusions.

The lack of positive aid from the bacteriological laboratory constitutes by itself a sufficiently serious difficulty in the epidemiological study of any supposedly infectious disease; but in the problem of the common cold this deficiency is associated with a lack of clinical definition. The fundamental importance of this is indicated by recalling the general process whereby proof of specific etiology is established.

In the usual order of procedure, the first stage in such proof is recognition of a distinctive clinical-pathological process which serves to identify individual cases with each other and to differentiate them from other diseases. It is the distinctiveness of this reaction which establishes the presumption that the cases manifesting it are due to a common cause which is different from that operative in cases where this clinical reaction is not found; and this presumption of specific (not necessarily infectious) causation is of fundamental importance to further investigation, forming a definite foundation upon which to assemble facts pertaining to the nature of the cause. Moreover, the character of the clinical reaction frequently suggests, by analogy with other diseases, that it either is or is not due to a specific microorganism.

In seeking to test the hypothesis of a specific cause and to learn

something of its nature and the mechanism of its action, we proceed by either or both of two methods: (1) by observation and analysis of special circumstances associated with the natural occurrence of the disease; or (2) by experimental methods, including in this category bacteriological and immunological procedures.

These several stages of proof may proceed coincidentally, or their order may be reversed, so that clinical differentiation may be derived originally from bacteriological observation, as in the distinction between typhoid and paratyphoid fever. But regardless of the sequence, the significance of both epidemiological and experimental evidence, as indicating a specific etiology for the disease in question, depends upon the distinctiveness of the pathological process which constitutes the disease. Obviously it is essential to the proof of specific etiology that the effect as well as the cause be specific.

As regards the common cold, what seems to be the most fundamental difficulty is that we have been unable to identify a clinical-pathological process which is sufficiently distinctive to be confidently accepted as specific. This affects both experimental and epidemiological studies. For example, various observers have succeeded in reproducing, under experimental conditions, reactions which more or less resembled the common cold or influenza, but the experiments have been indecisive because of uncertainty as to whether the experimental disease actually was identical with that occurring naturally in man. For epidemiological investigation a primary requirement is to mark off for study a clinical unit so distinctive as to justify the presumption that it coincides with an etiological unit.

In attempting to locate such a unit, we may begin by excluding from consideration diseases such as measles and the pollen fevers which exhibit symptoms more or less resembling those of the common cold but with other characteristics which readily differentiate them. This leaves in the field a rather large family of what we may call the minor respiratory diseases, all characterized by acute catarrhal inflammation of some portion of the respiratory tract, and a constitutional reaction of moderate severity, manifested by such symptoms as general malaise, headache, aching in the body and limbs, and perhaps fever. In addition to what usually would be called "colds," this family includes cases which, by present usage, are variously designated as influenza, grippe, acute bronchitis, tracheitis, laryngitis, and pharyngitis, respectively, or by some combinations or equivalents of these terms. Granting that these designations correspond to clinical pictures which actually are in some degree different, the question is whether this or any other classification divides the family into groups

of cases which are clinically so distinct as to justify the presumption that the cases within each group are due to one common cause, which is different from the cause of each other group.

Townsend and Sydenstricker¹ have investigated this question by statistical analysis of the clinical records of all the cases of minor respiratory disorders reported during two years in a large group of families, the records being furnished by observers, most of whom were physicians. Assembling the reported cases into four main diagnostic groups, viz.: colds, bronchitis, sore throat, and influenza, they found that these groups differed from each other only in the relative frequency and prominence of symptoms which were more or less common to all, so that the groups overlapped. Moreover, they found that in reporting cases the observers frequently used combinations of the four principal diagnoses, so that altogether more than a dozen diagnostic classes were represented. Interposing the various combinations between the main groups the result is a graded series of variation in clinical types, so that no group differs from its nearest neighbor sufficiently to justify a strong presumption of specifically different causation.

In a smaller but somewhat more intensive study which is now in progress in Baltimore we have observed all the cases of minor respiratory disorders occurring in a group of families in the course of a year. Within the whole series the range of variation in symptoms noted is very wide, extending from acutely febrile cases, conforming to the classical descriptions of epidemic influenza, to simple coryza or tracheitis, with little or no constitutional disturbance. If these extreme types were taken by themselves, they would seem to differ widely enough to justify the inference that they were due to quite different causes; but when the whole series is classified we find, as did Townsend and Sydenstricker, that the extremes are connected by a gradation of intermediate types, so that one does not know where to draw lines of demarcation.

The conclusion drawn from these two studies, namely, that the different clinical types of minor respiratory disorders merge into each other by graded variations, is not at all inconsistent with the fact that separate types are generally recognized in medical literature, for careful reading of the type-descriptions as given by representative writers shows that where lines of differentiation are drawn they are either arbitrary or quite indefinite.

I think then, that if we take into account only *clinical* evidence, it is an open question whether the whole family of these minor respiratory diseases should be considered as varying manifestations of a

single specific cause or as including an indefinite number of separate etiological groups. It is not necessary here to present any argument on either side of the question, or to discuss the prospect that more definitive clinical evidence may be discovered. The point is simply that the clinical evidence now available, taken by itself, does not justify any strong presumption either that the whole family is, or that it is not, a single etiological unit.*

Since neither clinical nor bacteriological observation has enabled us to mark off a definite group of cases which we may assume coincides with an etiological unit, we are in a dilemma with respect to epidemiological studies. If we begin by setting up a restricted clinical definition of the common cold, and confine epidemiological observations to cases coming within this definition, we may be making the same mistake that our forefathers made when they failed to identify membranous croup with other forms of diphtheria, and therefore run the risk of missing important epidemiological associations. On the other hand, if we include the whole family of minor respiratory diseases in one category, we may be obscuring, in the composite, distinctive epidemiological characteristics of its separate components, as would be the case if all the acute exanthemata were thrown into one undifferentiated group, so that facts concerning smallpox were confused with those pertaining to measles and scarlet fever.

The only way out of the difficulty seems to be to include the whole group of minor respiratory diseases in epidemiological studies, but with such detailed clinical and bacteriological records of individual cases as will permit any desired clinical groupings; then to ascertain whether any tentative groupings on a clinical or bacteriological basis correspond to significant epidemiological differences. This procedure has the merit that it involves no assumption as to the unity or diversity of causation for the group as a whole and that it affords the possibility of testing the significance of indistinct clinical differences by matching them against corresponding differences in epidemiological characteristics. However, the method is extremely laborious to carry out, even on a small scale, and obviously small scale studies do not suffice. Comparisons with respect to such features as rate and extent of geographic distribution require observations of the broadest scope.

The principle of seeking by epidemiological characteristics to supplement indistinct clinical differentiation of diseases is, of course, not new. It has been applied for many years in the study of epidemic

* It may be added that this is the usual view, for while many students of the subject, perhaps most of them, consider epidemic influenza a specific disease, distinct from endemic grippé and severe colds, they usually admit, more or less explicitly, that the differentiation is based partly upon epidemiological considerations. It may also be added that for the present bacteriological examination affords no significant basis for differentiation.

influenza, and less extensively in studies of the common cold. For instance, Townsend and Sydenstricker, in the study previously referred to, present statistical analyses of the seasonal and age distribution of cases classified clinically as colds, bronchitis, sore throat, and influenza, respectively, which show that as regards these epidemiological features the several groups differ from each other. To cite only one example, the age distribution of influenza differs from that of colds in their series; but granting that the differences are significant in a statistical sense, the question arises whether they are sufficient to indicate different specific causes.

A possible interpretation is that the age of the individual affected may be a factor in influencing the type of reaction to the same specific cause, as is true in diphtheria, where we find quite different age distributions for the laryngeal and pharyngeal forms of this disease. Likewise, such epidemiological differences as Jordan and others² have demonstrated between pandemic and inter-pandemic influenza present similar difficulties of interpretation; and it may be said generally of studies made upon this principle that the difficulties encountered in interpreting their data are even greater than those of collecting them.

CONCLUSION

In conclusion, it appears that the central problem involved in the epidemiology of the common cold is that of its relation to epidemic influenza and other members of the general family of minor respiratory diseases. Two of the approaches to this problem are at present being vigorously attacked by bacteriological and epidemiological studies, respectively; but the more direct approach, by way of clinical and pathological research, has received far less attention.

Considering that the problem is primarily one of identifying a pathological process, and that such identification appears to be fundamental to either bacteriological or epidemiological proof, the most urgent present need in the investigation of the common cold seems to be for more intensive clinical study of the whole group in which it falls.

Hospital Facilities for the Treatment of Cancer

SUSAN M. WOOD

Executive Secretary, New York City Cancer Committee, American Society for the Control of Cancer, New York, N. Y.

THE New York City Committee of the American Society for the Control of Cancer, with the approval and coöperation of the Commissioner of Health and the Commissioner of Hospitals, in 1929 made a preliminary survey of the field to ascertain what hospital facilities are available in the Metropolitan area for the treatment of cancer. The results were valuable chiefly because of the details obtained for the use of the Information Bureau of the committee. This bureau receives a large number of inquiries from persons who have cancer and are in need of hospital care, either free or paid, or who fear that they may have the disease and wish to be examined and if necessary properly treated. It is the custom of the bureau first to find out if the applicant has a physician to whom recourse should be had, and if not, to recommend one or two of the hospitals and clinics on its lists.

The need for hospital facilities for the treatment of cancer is shown by the following: The population of the City of New York during 1929 was estimated at 6,064,484. The total number of deaths in the city during the year was 77,482, of which 7,848, more than 10 per cent, were reported as due to cancer.

Totals by boroughs are given in Table I. These figures cover only the deaths certified as due to cancer. As cases of the disease are not reported to the Health Department, there are at present no means of estimating how many persons suffer from it, nor what ratio there is between the number of deaths and the total number of cases. It is, however, admitted that the average case of the disease runs a course of 3 years, which would mean that last year there were 23,544 persons in New York alone in need of treatment. But this again does not include those successfully treated by surgery or by radiation. Every physician knows that there are such patients, and that with better public understanding of the subject and of the good results obtained

TABLE I

TOTALS BY BOROUGHES

	Estimated Population	Total Deaths	Deaths from Cancer
All boroughs	6,064,484	77,482	7,848
Manhattan	1,689,419	28,033	2,662
Bronx	977,819	10,952	1,254
Brooklyn	2,342,781	26,690	2,705
Queens	899,791	9,816	1,040
Richmond	154,674	1,991	187

by early treatment, the number is constantly increasing. Two things are essential: the providing of adequate facilities for the treatment of the disease; and bringing the sufferer to the hospital or clinic when the disease is still in an early stage and the chances for cure are more favorable. The latter is the particular function of the American Society for the Control of Cancer. The most skilful surgeon and the best equipped radiotherapist are alike helpless to control the disease unless patients reach them in an operable condition or at a stage when radiation is effective.

In order to secure the desired information, a questionnaire was prepared and sent to all hospitals in the area then under the jurisdiction of the committee, comprising the five boroughs and the counties of Nassau, Suffolk, and Westchester. One of the chief facts brought out by the questionnaire was the difficulty of obtaining accurate statistics on cancer treatment. In the majority of institutions cases of cancer are received in the general surgical wards, and no separate records of cases either in the hospital or after discharge are kept.

In a report issued recently by the Welfare Council, *A Health Survey of New York City*, the authors state:

The bed capacity specially assigned to cancer patients in New York City is approximately 838 beds, 460 in special cancer hospitals, 289 in homes for incurable cancer patients, and 89 estimated to be used for cancer cases in institutions for the chronic sick that receive cancer patients. Of these 838 cancer beds, 264 are in municipal and 574 in voluntary institutions. In addition many cancer patients occupy beds in general hospitals, but the number cannot be computed. In 1927, Mount Sinai Hospital with a total of 13,000 admissions had 675 cancer cases, that is, about 5 per cent of all admissions.

The number of cancer patients at one time in most of the institutions of New York City that receive cancer cases will be shown by the census of the chronic sick, which has been taken as part of the study of chronic illness now being made by the Research Bureau of the Welfare Council.

Memorial Hospital, in 1926, received 2,390 applications for admission, 542 of which were declined as unsuitable. The actual number of admissions was 2,032, of which 495 were free ward cases, 1,000 paid ward rates, and 537 private room cases.

Five cancer institutions—Memorial Hospital, the New York City Cancer Institute, Brooklyn Cancer Institute, House of Calvary, and St. Rose's Free Home—in 1927 received a total of 3,975 patients. The number of cancer cases among the 1,095 admissions of the Skin and Cancer Hospital is not known, nor the proportion of cancer cases among the patients of other institutions for chronic diseases.

Replies to the committee's questionnaire were returned by 93 hospitals which receive cancer patients. Of these, 4 received only patients in the late stages, when no cure is to be hoped for, and the need is for frequent surgical dressings and a comfortable place to die. These were St. Rose's Free Home (89 beds) and the House of Calvary (100 beds), in Manhattan and the Bronx; the Home for Dependents, a municipal institution, in Richmond; and Rosary Hill Home (100 beds) in Westchester.

St. Rose's Free Home and Rosary Hill Home are maintained by the Servants of Relief solely for the care of the poor and hopeless cancer patients. This care is entirely free. The House of Calvary is also maintained as a free home for incurable cases.

Of the 89 other hospitals, all received cancer patients in the early stages requiring operation; 73 received patients in the later stages for surgical treatment; 47 received patients for treatment by radiation with either X-ray or radium; and 6, in addition to those already listed, regularly cared for patients in the last stages. These last are the New York City Cancer Institute (Welfare Island) and Montefiore Hospital, in Manhattan and the Bronx; Cumberland and Kings County Hospitals, in Brooklyn; and Ossining and St. John's Riverside Hospitals in Westchester. The New York Skin and Cancer Hospital cared for any patients in late stages of the disease who had been formerly treated at the institution; and St. John's Hospital, Brooklyn, contemplated the establishment of a special department for inoperable cancer patients. In many of the general hospitals, patients in a hopeless state were received and cared for pending their removal, when possible, to one of the above institutions or to one of the homes receiving only the incurables; in some cases, when beds were available, such patients were held until death.

Thirteen received only those in the early stages for operation.

At all of these hospitals, cancer patients were admitted in the regular surgical services, and no special assignment of beds was made, so that the total number available is indeterminate. The majority of the hospitals reported that from 1 to 5 per cent of their bed capacity was occupied by cancer patients. The Jewish Memorial Hospital in the Bronx reported 10 per cent of cancer patients.

During 1929 there were in New York 6 hospitals devoted to or with special services for the treatment of cancer in any and all stages. See Table II.

Cancer patients applying at the general hospitals in any of the boroughs and found to be unsuitable for treatment were usually referred to one or the other of these institutions. In none of the other boroughs or counties of the district were any provisions made for the treatment of cancer patients in advanced stages.

* Since this information was gathered, the Cancer Division of Cumberland Hospital has been abandoned, and the patients removed temporarily to other hospitals, pending the erection of a modern building.

Thirty-eight of the hospitals were equipped to give treatment with X-ray; 45 reported that they were equipped to give radium treatment. In some of these the radium used was the property of the hospital, but in the majority of cases it was privately owned, usually by members of the attending staff. Some of the hospitals used only radium emanation which was purchased as needed.

The largest stock of radium was owned by the Memorial Hospital which had 4 gm. belonging to the hospital and 4 in the ownership of special trustees. One-half of this amount was kept in solution and only the emanation was used; the other half was used in element pack.

The New York City Cancer Institute had the use of 2 gm. of radium owned by the Department of Hospitals, and had an emanation plant on Welfare Island, with a yield of about 700 M.C. daily. This emanation was supplied in seeds and applicators to other city hospitals when needed. The element itself was not used in treatment.

Bellevue Hospital had the use of 1 gm., also owned by the Department of Hospitals. Here the element was used.

Beth Israel Hospital owned 236 mg. of radium, and expected to purchase an additional gram and install an emanation apparatus.

The Manhattan Eye, Ear, and Throat Hospital had the use of 206.128 mg., one-half of which was owned by the hospital, while the other half was private property. Other hospitals having radium are shown in Table III.

In many hospitals radium emanation was used in suitable cases, the chief sources of supply being the Memorial Hospital and the New York City Cancer Institute.

Thirty-one hospitals stated that radiation alone was sometimes used in operable cases, depending on the region involved and the type of growth, and occasionally also on the patient's own preference; 27 stated positively that no operable cases were treated by radiation only.

There appeared to be very little specialization among the surgeons treating cancer, except in the special hospitals, such as the Manhattan Eye, Ear, and Throat, the Memorial, the New York Skin and Cancer, and the Sloane Hospital for Women.

No special effort was made to secure autopsies on cancer patients in the general hospitals; they were performed when permission was obtained. But as a matter of fact, the cancer mortality in the general hospitals is small, as comparatively few patients are held until death. No definite figures were available.

Out-patient departments equipped to make diagnoses in cases of cancer were reported in 70 hospitals, the charge for the examinations being the usual clinic fee only, that is, ranging from nothing to \$5.00, with an average of \$.25 to \$.50.

Patients applying at the clinic and found to have cancer or suspected of having cancer were usually sent into the hospital for treatment or observation, though in some cases they were referred directly to the special cancer hospitals.

Laboratories properly equipped for the examination of tissues for diagnosis were maintained by 78 hospitals, and in every case but 2 were in charge of a physician. The exceptions were the Midtown Hospital and St. Mary's Free Hospital for Children. The latter has no adult patients; and on occasions when diagnosis was necessary material for examination was sent to the New York Hospital.

All but 7 of the hospitals with laboratories were equipped for the making of frozen sections for immediate diagnosis during an operation.

BROOKLYN

Methodist Hospital	200
St. Mary's Hospital	100

Eight hospitals were without laboratory facilities; in one of these, however, a laboratory was under construction at the time the report was made. These hospitals send tissue for diagnosis either to the State Institute in Buffalo, to Bellevue Hospital, or to private laboratories in New York.

The system of following-up treated and untreated cases of cancer varied widely. In the general hospitals this usually was done as a part of the routine follow-up of all cases by the office, the out-patient department, or the social service workers.

The Presbyterian Hospital reported that it considered its follow-up clinic the best in the country, both treated and untreated patients being included. The cases were followed every 3 months, and the reports kept in a special section of the record room.

The Memorial Hospital reported that all cases were followed, the interval time being decided by the attending physician; in some cases patients were urged to report for examination as often as every 2 weeks.

Twenty-seven hospitals do not have a follow-up of either treated or untreated patients, though in almost all institutions the patient on discharge is urged to report for examination once a year, or oftener, to the hospital or to his own physician.

In some hospitals the follow-up was left entirely to the different services, each service being supposed to sustain its own.

In almost all cases where any regular follow-up was carried on by the hospital the returns were kept in the regular files, not as separate records.

Fifty-three hospitals reported that attempts were made to discover and treat precancerous symptoms—patients showing such lesions being kept under observation. Twenty-one hospitals reported definitely that no such attempts were made.

These figures indicate the inadequacy of provisions in the Metropolitan area for the hospitalization of patients suffering from malignant disease. Since then the City Department of Hospitals has begun the formulation of plans which will greatly increase the facilities and usefulness of its Division of Cancer.

The need for more adequate care for all other classes of cancer patients still exists, and calls for the development of special cancer hospitals, of cancer institutes connected with teaching institutions, and of special cancer services in general hospitals. With this increase in clinical facilities should go an increase in the facilities of the laboratory, as well as of the social service departments in charge of the follow-up work.

Training and Personnel*

THE following tables similar to those published in previous years present the data concerning students registered in schools of public health, and the public health degrees granted in the calendar year 1929.

* It is impossible to separate students taking degrees in public health from those taking biological courses.

† A course leading to a degree in public health is no longer offered.

‡ There were 7 other students doing full-time work but not candidates for any degree.

** The School of Hygiene and Public Health has been discontinued. Provision is now made in the graduate school of medicine for the registration of students applying for this work.

* Report of the Committee of the American Public Health Association presented at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October, 1929.

The committee has collected certain data concerning positions for which various schools of public health were asked to recommend candidates. The information concerning the salary range of these positions was very incomplete. University of California, University of Chicago, Columbia University, Harvard University, University of Michigan, and Yale Medical School, supplied the data presented in the following table.

TABLE III

KINDS OF PEOPLE WANTED

	Number	Salary Range
Teaching Positions		\$2,300-\$5,000
Physiology	3	
Hygiene and Public Health	5	
Health Education (College)	2	
Health Education (Public Schools)	2	
Home Economics	1	
Bacteriology	2	
Nursing Education	10	
Health Officers, Commissioners or Administrators		\$3,500-\$6,000
County, City and State	20	
Executive of Community Council	1	
Obstetrician, Bureau of Infant-Maternal and Child Hygiene	1	
Physicians		
School and College	6	\$4,000-\$8,000
Industrial	3	\$19,000 (Only salary given)

Amendment of Child Labor Legislation in Germany

THE temporary regulations governing the employment of young workers in Germany in glass works, in rolling mills, in iron works, and above ground in coal mines, have recently been amended to agree with the provisions included in the labor bill which is now pending in the Reichstag, but which will probably not be enacted for some time.

While previously a child could go to work in these industries at the age of 13 if he had completed the required school course, and in any case at the age of 14, the minimum age for employment in certain processes is now placed at 14, if the child has finished the prescribed school course; otherwise he must wait until he finishes the course. The minimum age for work in certain unhealthful processes is raised from 14 to 15 and in certain others from 16 to 18 years. Further limitations are placed on the number of exceptions to the prohibition of work at night of boys under 16, and provision is made for the gradual abolition of such night work. (The night work of women and girls was prohibited a number of years ago.)—*Reichsarbeitsblatt*, Berlin, No. 10, 1930.

MENTAL HYGIENE

IN most of our commonwealths the administration of mental health measures has been conferred on state authorities rather than local. The state has maintained hospitals for the mentally ill, and schools for the defective, and has brought clinics to many communities. It has also assisted in removing the mentally sick from their homes or other places, when private institutions, the police, or the poor authorities have identified the patient and the court has authorized his detention. Only gradually has it been thought that these problems may be problems of public health.

Since most diseases involving the state of mind are not actively communicable, the health officer is not commonly charged with any duties concerning them. Nevertheless, such illnesses if not given prompt and appropriate treatment may be more dangerous to the individual than leprosy and more dangerous to the community than smallpox. Specifically, a man who is mentally sick may put a violent end to his life. This may terminate the usefulness of a person who has every expectation of recovery and restoration to usefulness. Furthermore, if the patient be excited rather than depressed or if he be the victim of mistaken ideas concerning the relation of people about him to his affairs, he may, by recklessness or aggression, cause the death of others, thus inflicting an injury more sudden than and as irreparable as if he communicated diphtheria or typhoid fever. Common illnesses that can cause the death of a sick person or of other

persons are concerns of public health officials and should be so recognized.

The apprehension and temporary care of the mentally ill, his danger and exploitation, his assignment and removal to proper hospitals are services necessary in every community. These services must be performed by public authorities, because the sick person may be at a distance from his home and his friends, or his friends may be inadequate to care for him. It has been customary to think of these problems as belonging to the police, but since we are no longer willing to think of the mentally sick person as a criminal, and since public care for all those who are mentally ill has assumed generous proportions in almost every state in the Union, we lack justification for continuing to turn these medical problems to departments of local government that are equipped to deal only with minor phases of the problem, instead of the heart and core of it.

It is now time to go to the root of the matter and declare that mental illness unless privately cared for should receive the oversight of medical authorities from the moment it comes to the attention of any public authorities. In the case of mental illness that requires any action on the part of community officials, the jurisdiction of the health officer should be invoked as promptly as for a case of smallpox. He is the official who should be responsible for diagnosis, temporary care and treatment, and all preliminaries to the admission of the patient to an appropriate hospital, including commitment if that be necessary.

It may be argued that the health officer is not an expert in mental diseases and might therefore be inadequate to deal with these problems. The reply is obvious: neither are other physicians in the community experts in mental diseases. The subject of mental illness is not so abstruse that it must always be placed in the hands of a specialist. The health officer has the machinery for investigation, and if in doubt about the diagnosis is in a much better position to obtain a consultation than is a police captain or the overseer of the poor. To him should be granted authority to make necessary expenditures for temporary care and transportation. He should also be given authority to commit on his own certificate to a mental hospital for a period of observation.

It may be added that this program, novel as it may appear to many communities, has already been in operation for 15 years in the State of New York. Its adoption has resulted in marked improvement in the care of mentally sick, pending their removal to state hospitals. The extension to the health officer has resulted in prompt action instead of the delay that brings no advantage to any interested

person, and merely satisfies some outworn conception of public caution and security. It puts power into the hands of the health officer, affords comfort and security to the community, and assures the patient that speedy relief which his condition demands.

CANCER

THE increase in cancer is causing much concern in every part of the world. Health departments are being urged to take up the cancer problem as a public health matter, just as tuberculosis and other prevalent diseases have been and are now being handled. That much can be accomplished has been definitely proved in the case of tuberculosis as well as practically every other contagious disease. Cancer is not contagious, as far as we know, and this is probably one reason why health departments have been slow to take it up as a part of their regular functions.

Among the major causes of death, cancer now stands second, being exceeded only by heart disease. It is estimated that it causes at least 125,000 deaths yearly in this country, and the rate is steadily increasing. This increase has been the subject of much discussion, some holding that it is apparent, not real, due to better diagnosis. The weight of evidence, however, appears to be in favor of an actual increase.

The search for the cause of cancer is world-wide. Every so often a germ is discovered in cancerous tissues and held to be the causative organism, but no such finding has been able to withstand the tests of criticism. All remember the tremendous excitement over the alleged discovery of the germ by photography by two English observers a few years ago. Without passing an opinion on the matter, it can be definitely stated that this germ has not been cultivated, and that the researches which attracted so much attention have not advanced to a satisfactory stage, as far as the control of the disease goes, and the causative factor is still undiscovered.

It is known that certain industrial occupations in which tar and its derivatives are used involve a definite tendency to the production of cancer, and experimental work with these products has shown their cancerogenic properties.

The American Society for the Control of Cancer began its work in 1913, and has accomplished much in spreading information through the meetings held throughout the country during Cancer Week, as well as by publications. People now recognize that there is no disgrace in having cancer; that it is a disease to which all are liable, those

who escape being more fortunate than the sufferers. This is about all that can be said on this point at present, but it has had a decided influence in overcoming the tendency to concealment, especially as it is coupled with the assurance that cancers are local in the early stages, and many can be cured by competent physicians.

So far, only two state governments have definitely recognized their responsibility for the control of cancer—New York and Massachusetts. The former has recently made appropriations for the purchase of radium to be distributed among the hospitals of the state. The City of New York has led in municipal work since, in 1923, a City Cancer Institute was established, which secured the free services of excellent surgeons, and has provided two grams of radium, as well as other equipment. The city is now proposing to build a 400-bed hospital in connection with Bellevue, at a cost of $4\frac{1}{2}$ million dollars. It is hoped that these examples will have their influence on other cities and states.

Our most earnest endeavors must be expended in educating the public, not only in the known facts concerning the disease, but in teaching them to avoid the "cancer specialists," ghouls who swarm every part of the country. There is no more repulsive business in the world than that conducted by these quacks, fattening, as they do, at the expense of human suffering and life. The public should also be taught the limitations of X-ray and radium treatment, and be warned that they are powerful agents, extremely dangerous in the hands of any but the best informed and experienced practitioners, and with limited powers, even in the best of hands.

CONSTITUTION AND BY-LAWS, AND CONSTITUTION FOR SECTIONS, AMERICAN PUBLIC HEALTH ASSOCIATION

As Amended by the Governing Council at the Fifty-eighth Annual Meeting,
Minneapolis, Minn., September 30-October 5, 1929

CONSTITUTION

ARTICLE I NAME

The name of this Association, incorporated under the laws of Massachusetts, is the American Public Health Association.

ARTICLE II OBJECT

The object of this Association is to protect and promote public and personal health.

ARTICLE III GOVERNING COUNCIL

A. *Composition*: There shall be a Governing Council consisting of:

1. The officers of the Association.

2. Thirty members of the Council, to be elected by and from the Fellowship of the Association, for three-year terms, one-third retiring each year. These members of the Council shall be nominated and elected as provided for in the By-laws.

If one of these members is elected a Section Chairman, Vice-Chairman, or Secretary, or appointed the representative of an Affiliated Society, a new Councilor to fill such vacancy shall be elected by the Governing Council.

3. The Chairman, Vice-Chairman, and Secretary of each Section.

4. Representatives to be appointed by Affiliated Societies as provided for in the By-laws. Such representatives shall be Fellows of the American Public Health Association.

5. The elective members of the Council of the Health Officers Section.

B. *Terms*: Terms of Councilors shall begin at the end of the annual meeting when elected, and shall terminate at the end of the annual meeting at expiration of term; provided that Councilors shall have the right to attend meetings of the Council in an advisory capacity as soon as elected.

C. *Re-election*: After two consecutive terms, an elective Councilor shall be ineligible for re-election to the Council during one Association year.

D. *The Officers of the Association* shall be the officers of the Council.

E. *Functions*: The functions of the Council shall be:

1. To establish policies for the Association and for the guidance of the Executive Board and the officers.

2. To establish Sections of the Association; to combine or discontinue them when necessary; to maintain coördination among them; and to formulate general rules governing the policies of the Sections.

3. To submit to the vote of the Association all resolutions which have received the approval of the Governing Council.

4. To elect and establish qualifications for Affiliated Societies, Fellows, and Honorary Fellows as provided in the By-laws.

5. To elect the Executive Board and the officers of the Association.

6. To receive from the Executive Board at its first session, at the time and place of the annual meeting of the Association, a definitely formulated statement of a program of the major activities proposed for the ensuing year. To determine at the annual meeting of the Association in general outline the allocation of Association moneys in the budget for the ensuing year. To require a report from the Chairman of the Executive Board in which the work, the accomplishments and the financial status of the Association during the year preceding such annual meeting shall be reviewed.

7. To publish after each of its meetings an abstract of the minutes of such meetings.

F. A *Quorum* of the Council shall consist of ten Councilors.

G. *Meetings* of the Council shall be called by the Executive Secretary at the request of the President, or at the request in writing of any twelve Councilors. In the latter case, the call to meeting, issued at least twenty days in advance, shall state the purpose of the meeting.

ARTICLE IV OFFICERS

The officers of this Association shall be a President, a President-elect, three Vice-Presidents, an Executive Secretary, a Treasurer, and the Chairman of the Executive Board. The officers, with the exception of the Chairman of the Executive Board and the Executive Secretary, shall be elected by written ballot of the Governing Council as provided in this article and in the By-laws. The President-elect shall serve as such from the close of the annual meeting at which he was elected to the close of the next annual meeting, when he shall au-

tomatically become President. As President he shall serve to the close of the next succeeding annual meeting. Other officers shall serve from the close of the annual meeting when elected, until the close of the next annual meeting, and all officers shall serve in any case until their successors are elected and qualified. A majority vote of the Councilors voting shall be required to elect, and if no candidate receives a majority vote on the first ballot, the candidate receiving the smallest number of votes shall be dropped after each ballot in succession until a majority vote is obtained. The Chairman of the Executive Board and the Executive

Secretary shall be elected by the Executive Board, which Board shall define the duties and authority of these officers, respectively.

ARTICLE V AMENDMENTS

This Constitution may be amended by a two-thirds vote of the Fellows of the Association present and voting at an annual meeting, provided that the specific amendment to be acted upon is published in the official publication of the Association not less than thirty days prior to the meeting, and provided further that the amendment has received the approval of the Governing Council.

BY-LAWS

ARTICLE I MEMBERSHIP AND DUES

A. There shall be eight classes of constituents who may be elected from the United States, Canada, Mexico, Cuba, and such other countries as may be admitted to representation in the Association. This provision shall not apply to Honorary Fellows or Associate Members. The respective appellations, qualifications for election, and dues shall be as follows:

1. *Fellows*: Only professional health workers, who have been Members of the Association for at least two years, and of established professional standing (whether employed by public or private agencies or in independent private practice), shall be eligible for election as Fellows, provided that a Member shall be not less than thirty years old at the time the application for Fellowship is made, and provided, further, that the following persons shall be considered to have an established standing in the profession of public health, namely:

a. A person who has attained the degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, or other equivalent degree, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has attained an academic or professional degree involving training in public health, and who has been regularly engaged in public health work for four years, having rendered meritorious service in the public health profession, either as a health officer or in responsible charge of work in a state or municipal department of health or other official public health organization.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing equivalent to that required for Fellows under paragraphs "a" and "b."

d. A person regularly engaged in public

health work for at least five years, who has given evidence of special proficiency in the service of an official or unofficial public health organization, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

e. A teacher of public health or one of its constituent sciences. As such he shall have attained distinction as an expounder of the principles of public health or its constituent sciences and he shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch of public health service, and who has attained a professional standing equivalent to that required for Fellows under paragraphs "a" and "b."

The application for Fellowship shall be made on an approved form and shall be sponsored by two Fellows of the Association who shall be Fellows of the Section with which affiliation is desired, provided, however, that when affiliation with a Section is not desired, the sponsors may be any two Fellows in good standing in the Association. Fellows without Section affiliation shall be known as unaffiliated Fellows.

When the application has been duly sponsored and otherwise completed, it shall be transmitted to the Administrative Office of the Association, which will make note thereon of such knowledge as it may have concerning the standing of the applicant in the Association. The application shall be forwarded by the Administrative Office to the Secretary of the Section in which affiliation is desired, for the

approval of the Section Council, and when acted upon by the Section Council, it shall be returned to the Administrative Office by the Secretary of the Section, after he has made endorsement on the application of the action of the Section Council. When the application is for unaffiliated Fellowship, the Executive Board of the Association shall act in place of the Section Council. When the application has been approved by a majority of the Section Council or the Executive Board, as above provided, it shall be voted upon by the Governing Council, provided the name of the applicant shall have been officially published at least fifteen days in advance, and provided further that the application shall have been approved by the Committee on Fellowship and Membership.

A Fellow may belong to and vote in only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Fellows may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

The right to hold office or to serve as chairman of a committee in the Association shall be limited to the Fellows of the Association, whether Section Fellows or unaffiliated Fellows. The right to hold office or to serve as chairman of a committee in a Section shall, however, be limited to the respective Fellows in such Section.

The dues of Fellows shall be \$10.00 per year.

2. *Honorary Fellows:* Honorary Fellows may be elected by the Governing Council for distinguished service in public health. Honorary Fellowship shall not include voting power or payment of dues.

3. *Members:* Persons professionally engaged in public health work shall be eligible for election as active Members when sponsored by two Fellows of the Association. They may serve on committees, except as chairmen. Dues \$5.00 per year. A Member may belong to only one Section, but such affiliation may be transferred to another Section if approved by vote of a majority of the Council of the latter Section. Unaffiliated Members may become affiliated with a Section if approved by vote of a majority of the Council of the Section with which affiliation is desired.

4. *Associate Members:* Persons interested in public health shall be eligible as Associate Members. They may serve on committees, except as Chairmen. Dues \$5.00 per year.

5. *Sustaining Members:* Individuals or corporations interested in public health may be elected to Sustaining Membership. Dues \$50.00 or more per year.

6. *Affiliated Societies:* A state or provincial public health association or similar regional society including more or less than a state, primarily composed of professional public health workers and organized for the same general objects as the American Public Health Association, may be elected as an Affiliated Society, provided that not less than twenty of its active members and at least one-half of its active members are Members or Fellows of the American Public Health Association. Not more than one such society shall be admitted from the same area.

A society applying for affiliation shall submit a copy of its constitution and by-laws, its last annual budget, a roster of its members and such other evidences of its qualifications as may be required. It shall submit annually and at other times such reports on its financial standing, membership and other matters as may be required by the Executive Board of the American Public Health Association.

The Committee on Fellowship and Membership shall consider all applications for affiliation and report its recommendations to the Governing Council.

The annual dues of Affiliated Societies shall be one per cent of their gross annual income, the minimum dues per society being \$10.00 per year.

Each Fellow, Member, Associate Member, and Affiliated Member of the American Public Health Association shall be a member of the Affiliated Society to which he is eligible and no person eligible for election to an Affiliated Society shall be admitted to Membership, Associate Membership or Affiliated Membership in the American Public Health Association unless such person has qualified or at the same time qualifies as a member of an Affiliated Society.

For every Fellow, Member, Associate Member or Affiliated Member paying annual dues to the American Public Health Association, the American Public Health Association shall remit to the Affiliated Society of which such person is a member the sum of \$1.00 per annum.

7. *Affiliated Members:* This class of membership shall include all active (namely professional) members of Affiliated Societies, and in areas where no Affiliated Societies exist such other professional sanitarians as may be elected to this grade. Dues \$1.00 per year.

8. *Life Members:* Upon the recommendation of the Committee on Fellowship and Membership any individual member of the Association may be elected a member for life. Election to this grade shall not affect the privileges held by such individual in his previous grade of membership. The dues for Life Mem-

bers shall be \$100.00, payable within one year after election, and this payment by such member shall exempt him from any further dues.

B. Election: The election of Fellows (see A1 above), Honorary Fellows, Life Members, and Affiliated Societies shall be by the Governing Council.

The election of Members, Associate Members, and Sustaining Members shall be by the Executive Board.

Three-fourths of the votes cast shall be requisite for election.

Upon the recommendation of the Committee on Fellowship and Membership the Governing Council may discontinue the Membership, Fellowship or affiliation of any constituent. Three-fourths of the votes cast shall be necessary for such action.

C. Dues: Dues are payable annually in advance. All constituents paying dues shall be entitled to receive the AMERICAN JOURNAL OF PUBLIC HEALTH and, or, such other publications as may be designated by the Executive Board, which shall determine the proportion of dues to be devoted to this purpose.

Constituents of any class whose dues are unpaid for six months or more shall be considered not in good standing. Constituents not in good standing shall not be entitled to vote, hold office or enjoy other privileges or powers of membership. Good standing may be resumed upon the payment of all arrears and dues in advance for one year, provided, however, the lapsed period is not greater than one year. The Administrative Office shall notify by registered mail all constituents who have been in arrears for a period of eleven months. The names of constituents in any class whose dues remain unpaid for one year or more shall be presented to the Executive Board which shall order the names of such constituents stricken from the Membership roll, provided, however, such constituents have been duly notified as hereinbefore provided in this paragraph. Constituents whose names have been stricken from the rolls in this manner may be again admitted in the manner provided for the election of new constituents in the class for which they make application, provided such person or organization complies with the eligibility requirements at the time the new application is made.

ARTICLE II GOVERNING COUNCIL

The thirty members of the Governing Council designated in Article III, Section A, Paragraph 2 of the Constitution, shall be nominated and elected as follows: There shall be a Nominating Committee composed of one Fellow elected by each Section at the preceding annual meeting, and an additional Fel-

low designated by the Executive Board, the latter serving as Chairman. This committee shall present to the administrative office at least two months before the next annual meeting the names of at least twenty and not more than thirty Fellows of the Association selected with due regard to geographical and Membership considerations as nominees for the Governing Council. The administrative office shall publish this list to the Membership. Upon the petition of twenty-five Fellows the Nominating Committee shall add the name of any Fellow to this list provided such petition is received fifteen days before the annual meeting. The time for closing the polls shall be determined each year by the Executive Board. The Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the annual meeting shall be declared elected to fill existing vacancies. Should two or more candidates receive the same number of votes the Executive Board shall, when necessary, determine by written ballot the order of precedence.

ARTICLE III EXECUTIVE BOARD

A. Composition: There shall be an Executive Board of nine members elected by the Governing Council, six of whom shall be past or present members of the Governing Council, and three of whom shall be the President, the President-Elect, and the Treasurer.

B. Terms: The terms of the President, the President-Elect, and the Treasurer as Executive Board members shall be one year each. The terms of the other members shall be three years each, expiring in rotation, two each year. The members of the Executive Board whose terms have not expired shall at the time of the adoption of this amendment continue in office until the expiration of the term for which they have been elected. At the annual meeting at which this amendment is adopted one member shall be elected for a term of two years and two members for a term of three years. Should a vacancy occur the Governing Council shall elect a member to fill such vacancy for the unexpired term. The terms of the members of the Executive Board shall begin at the end of the annual meeting at which they have been elected, and shall continue until the end of the annual meeting at expiration of term, provided that newly elected members of the Board shall have the right to attend meetings as soon as elected, and shall have no vote until installed.

C. Re-election: After two consecutive terms of three years a member of the Executive Board shall be ineligible for re-election during one Association year. This provision shall not apply to an officer of the Association.

D. Officers: The Executive Board shall elect from its own membership a Chairman who shall serve in that capacity for such term as the Executive Board shall determine. It shall also designate such other officers of the Board as it may require for the conduct of its business.

E. Duties:

1. To direct the administrative work of the Association.

2. To act as Trustee of the Association's properties.

3. To plan methods for the procurement of funds.

4. To recommend budgets for the Association's work.

5. To conform to the policies of the Governing Council in the conduct of its work.

6. To appoint the members of the four Standing Committees and to authorize and confirm the appointment of all other Association committees.

7. To transmit a report of its proceedings and transactions to the Governing Council at least thirty days before each annual meeting.

8. In general to carry out the policies of the Governing Council between meetings of the latter.

F. A Quorum of the Executive Board shall consist of four members.

ARTICLE IV OFFICERS

The officers elected by the Governing Council shall be nominated from the floor by that body.

ARTICLE V COMMITTEES

There shall be four standing committees of the Association as follows:

1. Committee on Fellowship and Membership.

2. Committee on Meetings and Publications.

3. Committee on Administrative Practice.

4. Committee on Research and Standards.

Organization: All of the Standing and Special Committees of the Association shall be authorized and appointed by the Executive Board unless otherwise provided for in these By-laws. Unless otherwise provided for all section committees shall be named by the respective sections, and the personnel of such committees shall be confirmed by the Executive Board. The appointments of all Association and Section committees unless otherwise provided for in these By-laws shall expire at the next annual meeting. The Chairmen of the Standing Committees shall be designated by the Executive Board. The Standing Committees shall designate from among their membership such other officers as they may require for the conduct of their business. Each com-

mittee shall control its finances and policies within limitations prescribed by the Governing Council and the Executive Board.

Composition and Functions:

1. The Committee on Fellowship and Membership shall consist of one Fellow to be elected by each Section and an additional Fellow elected by the Executive Board. At the time of the adoption of this amendment the Executive Board shall designate which five of the members of this committee shall serve for one year, the balance to serve for two years. Thereafter, those designated to fill vacancies shall serve for a term of two years.

This committee shall pass upon the eligibility of Fellows, Members and other constituents, in accordance with the provisions of the By-laws. It shall carry on membership promotion and shall discharge such other duties as are assigned to it by the Governing Council or by the Executive Board.

2. The Committee on Meetings and Publications shall consist of five Fellows. At the time of adoption of this amendment the Executive Board shall elect five Fellows to serve for one, two, three, four and five years respectively. Thereafter, members shall serve for a term of five years.

This committee shall prepare plans and a program for the conduct of annual and other meetings of the Association. All publications of the Association, its Sections and committees shall be issued under the direction of this committee, which shall also be responsible for the editorial and financial policies and management of all such publications.

3. The Committee on Administrative Practice shall consist of fifteen Fellows as follows: Twelve shall be designated by the Executive Board to serve for a term of four years, the terms of three members of this committee expiring each year. The remaining three members of this committee shall be the Chairman, the Vice-Chairman and the Secretary of the Health Officers Section.

This committee shall engage in the collection of information regarding current public health practices and analyze the material obtained to derive standards of organization and achievement. The findings and standards may be made available to public health workers through publications, information and field service under such conditions as the committee may establish. The committee shall also be able to contract in the name of the American Public Health Association with public and private health organizations to make health surveys and to render consultant service for pay. The committee will be responsible for the financial policies of its work and may employ

such personnel as is necessary to carry on its activities within its approved budget.

4. The Committee on Research and Standards shall consist of fifteen Fellows representative of the various Sections of the Association appointed by the Executive Board. In the beginning the Executive Board shall designate five who shall serve for a term of one year, five for two years, and five for three years. Thereafter members shall serve for a term of three years.

This committee shall be responsible for carrying out research and the development of standards in the technical branches of public health service and training, and coordinate such research and standardization. This committee shall also be charged with the duty of reviewing from time to time standards already established. No standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council.

ARTICLE VI MEETINGS OF THE ASSOCIATION

There shall be at least one annual meeting of the Association, held at a place to be selected by the Governing Council. All papers and reports presented at the annual meeting shall be the property of the Association for publication, unless this right is waived by the Committee on Meetings and Publications. Special meetings of the Association may be called by a majority vote of the Governing Council, the Executive Board, or the Association.

ARTICLE VII SECTIONS

The Executive Board shall approve rules and regulations relating to the government of the Sections, and to the appointment of administrative committees: Sections shall elect their own officers.

A. *Officers* of each Section shall be a Chairman, a Vice-Chairman, and a Secretary. The Chairman, Vice-Chairman, and Secretary shall be the representatives of the Section to the Governing Council of the Association.

B. *Terms*: New terms begin and old terms expire at the end of annual meetings. After five consecutive years in any elective Section office, except that of Secretary, a member shall be ineligible to reelection to that office during one Association year.

C. *The Chairman* shall preside at meetings of the Section.

D. *The Vice-Chairman* shall preside at meetings of the Section in the absence of the Chairman.

E. *The Secretary* of the Section shall prepare the scientific program of the Section for

the annual meeting, subject to the recommendations of the Section Council, and he shall submit same to the Committee on Meetings and Publications and shall keep the minutes, and other records of the Section, and shall transmit to the Secretary of the Association a copy of the minutes of both business and scientific sessions as soon as practicable thereafter. When unable to be present at meetings, he shall thoroughly instruct a substitute as far in advance of the meeting as possible.

F. *Section Council*: There shall be a Section Council composed of the three officers of the Section and five members, who shall be Fellows of the Section.

Terms of members of the Section Council shall be five years each. In the beginning one shall serve for one year, one for two, one for three, one for four, and one for five years.

Duties of the Section Council shall be:

1. To recommend papers, and to make general recommendations in relation to the annual meeting program.

2. To advise on Section membership.

3. To advise on Section policies.

4. To submit annually to the Governing Council through the Executive Board a report of the transactions of the Section.

5. To report annually to the Governing Council through the Executive Board on the plans, scope and policy of the Section during the succeeding year.

6. To formulate rules of procedure for the Section.

7. To approve and transmit to the Governing Council resolutions originating in the Section.

8. To advise on the publication of papers and reports presented at the Section meetings.

9. To advise with respect to the appointment of technical committees, sub-committees or Section representatives on committees of the Association.

ARTICLE VIII FINANCES

All remittances to the Association shall be deposited to the account of the Treasurer. The Treasurer shall be custodian of investments of the Association and shall disburse funds in accordance with duly authorized vouchers. With the approval of the Executive Board he may establish a drawing account for the Executive Secretary, who shall send to members of the Executive Board a financial summary of receipts and disbursements each month. Once each month, or oftener if called for, he shall also forward to the Treasurer and President an itemized statement of all expenditures. The Executive Secretary and the Treasurer shall be bonded at the expense of the Association in an amount to be determined

by the Executive Board. The books of the Association shall be audited annually by certified public accountants, to be appointed by the Executive Board.

ARTICLE IX AMENDMENTS

These By-laws may be amended by a two-thirds vote of those voting on the Governing

Council during the annual meeting, provided that twenty-four hours prior written notice thereof has been given. The By-laws may further be amended by a two-thirds vote of those voting at any meeting of the Governing Council called for the purpose, provided that notice thereof shall have been given at least fifteen days prior to such meeting.

*A complete list of Fellows and Members
of the American Public Health Association
is being prepared, and will be published
at an early date.*

ASSOCIATION NEWS

INSPECTION TRIPS, RODEO AND BARBECUE FOR A. P. H. A.
CONVENTION, FORT WORTH, TEXAS—OCTOBER 27-30, 1930

A. H. FLICKWER, M. D.

General Chairman, Local Committee

THE committee in charge of inspection trips has arranged a very interesting schedule. On Monday there will be a visit to the water filter plant which will be of interest to all sanitary engineers, chemists, and others who are interested in a modern water system. Fort Worth obtains its water supply from Lake Worth where it is brought from a conduit with a capacity of 50 million gallons per day to the filter plant.

This plant was completed in 1912 with a capacity of 5 million gallons per day, in 1917 it was increased to 10 million, and in 1923 to 20 million gallons per day. The city water works is an industry owned and operated by the City of Fort Worth, purifying, pumping, and delivering a commodity to its consumers the same as other public utilities.

The revenue from the sale of water is the only income. No part of the expense of this enterprise is borne by the taxpayers. The water works is required to be self-supporting, paying for all labor, materials, interest and maturities on outstanding obligations.

Another inspection trip on Monday will be to the Swift and Armour Packing Plants. This visit will require approximately 2½ hours, and the visitors will have an opportunity of seeing a modern packing plant in operation. The inspectors of the Bureau of Animal Industry will demonstrate the methods of meat inspection at this time.

On Tuesday there will be a trip to Terrell, Globe and Southwestern Laboratories. Terrell's laboratory will interest physicians and bacteriologists as

Fort Worth Sewage Disposal Plant from the Air

it is a very extensive laboratory with a large staff and does all of the laboratory work pertaining to public health, including bacteriology and chemistry. Globe Laboratory manufactures biologicals, and the Southwestern Laboratory does a great deal of commercial work.

On Tuesday there will also be a visit to Fort Worth's Municipal Airport. It is modern in every respect and one of the largest in the United States. It comprises 525 acres in all. There are 8 passenger air lines operating in and out of Fort Worth daily and 4 air mail lines. During the month of June alone, 3,524 passengers were carried in and out of Fort Worth by 845 ships. Fort Worth is the home port of some 150 airplanes, the majority of these being owned by citizens. During the convention, visitors may take airplane rides any time that they desire at the Municipal airport.

On Wednesday a special trip to the new sewage treatment plant has been arranged. The original plant, Imhoff

*Day Nursery Operated by the Department of
Public Health and Welfare*

with sprinkling filters, with a capacity of 8 million gallons per day, was constructed in 1923-1924 at a cost of \$800,000.00. The plant was enlarged in 1929 to a capacity of 16 million gallons per day at an additional cost of \$780,000.00. The enlarged plant is one of the most complete units in the country, as it comprises a combination of the Imhoff sprinkling filter system with the activated sludge methods, having secondary settling tanks, clarifiers, and di-

gestion tanks. The digestion tanks are equipped with gas collectors. All gas is metered and record is made with the view of determining the possibility of using it for power to operate the plant. It is now being used for heating the

*Health Center Operated by Department of
Public Health and Welfare*

buildings, digestion tanks and for fuel in the incinerator.

On Thursday there will be a trip to the various hospitals of the city including the new Methodist hospital, one of the largest in the south; Cook Memorial, one of the most beautiful; Children's hospital; Baptist; St. Joseph's; and others.

There will be several unscheduled trips to our various health centers, day nurseries, schools, etc. Fort Worth has 14 health centers, operated by the Department of Public Health and Welfare, which will be open to visitors, as it is the aim of the committee to have transportation ready at all times during the time that health centers, day nurseries, and schools are open to take small groups to visit them when they desire.

Another trip that will be made is to the Lancaster Yards of the Texas and Pacific Railroad which were recently completed at a cost of 5 million dollars. These railroad yards are modern in every respect, particular attention being given to sanitation and safety devices and should be of interest to civil, sanitary, and industrial engineers.

There will also be a trip around Lancaster, which is the source of Fort Worth, which is the source of Fort Worth.

Worth's water supply. On this trip visitors will have an opportunity to see some of the Texas countryside in late October when it is, indeed, most beautiful. There will be a tour of the city, including a visit to the new farm market and other modern markets in the various parts of the city. Fort Worth is noted for its excellent markets and they are always of interest to the visitors from the north and east because they display all of the fresh fruits and vegetables produced in this vicinity.

It is the intention of the entertainment committee to stage a barbecue and

rodeo, probably on Wednesday afternoon and evening. The rodeo will consist of the usual features offered at real ranch roundups—riding of bucking broncos, bulldogging of steers, calf roping, trick riding, fancy roping, etc. Fort Worth is the home of many rodeo stars. Most of them will have returned from their summer engagements and should be available for our program.

A barbecue will be in the hands of experts who have for many years barbecued beef, mutton, and pork over the open fire and basted it with the famous Texas barbecue sauce.

Fort Worth Public Market

ANNUAL MEETING PROGRAM

THE Preliminary Program of the scientific sessions will be published in the September issue of the JOURNAL.

During July a letter and descriptive folder were mailed to every Fellow and Member of the Association giving details of the post-convention trip of nine days to Mexico City.

Those attending the meetings are especially invited to stop over in San

Antonio, one of the most interesting cities in America. Letters of invitation have been received from several other nearby cities.

A letter giving full railroad information will be sent to the entire membership about September 10. The period of time over which reduced rates are available has been extended to take care of those going to Mexico City.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Control of Scarlet Fever—A questionnaire was recently directed to a number of city health officers inquiring concerning control measures now used for scarlet fever. The practice varies considerably in different cities and states. Twelve questions were asked and an answer given for each question describing the methods employed in the City of Detroit. The health officers to whom the questionnaire was directed have replied with the same general form of outline. With the purpose of giving this wider publicity and encouraging more discussion, this questionnaire is here printed in full.

I

Q. What is your definition of *isolation* and *quarantine*?

A. We reserve the word "isolation" to indicate the restriction imposed upon the case affected with certain communicable diseases in such a place and under such conditions as will prevent the direct or indirect conveyance of the infectious agent to the public.

The word "quarantine" is reserved for the restriction placed upon contacts with cases of certain communicable diseases. These restrictions vary with the disease under consideration, and also with the circumstances under which the patient is isolated.

II

Q. Do you date isolation of case from date of onset of disease, date of rash, or date of isolation?

A. It is our practice to date isolation from the day on which the patient was isolated, as is required by the regulations of the State Department of Health.

III

Q. What is the duration of isolation of simple uncomplicated cases of scarlet fever, and also of complicated cases of scarlet fever?

A. Simple uncomplicated cases of scarlet fever are isolated for a minimum period of 28 days.

Cases complicated with otitis media, if the same has developed during the course of scarlet fever, will be isolated for a minimum period of 28 days, or a maximum period of 56 days if the patient is isolated at home. The isolation will continue for 1 week unless the symptoms of otitis media subside in the meantime. If, at the end of 35 days, there is a discharge from the ear, the isolation period is terminated, but a warning sign is posted until the discharge ceases, unless a period of 56 days is exceeded, in which instance the case is released completely.

If the patient has been cared for in the hospital, cultures for hemolytic streptococci are taken from all abnormal discharges at the beginning of the 25th day. The patient is detained at the hospital until either the discharge has ceased or cultures from same are found to be negative for hemolytic streptococci on two occasions at least 24 hours apart, at which time the patient will be released.

Cases of scarlet fever complicated with rhinitis and sinusitis, or with pharyngitis and cervical adenitis, or skin lesions, empyema, etc., are isolated for the same periods as indicated above.

IV

Q. Is the period of isolation of cases determined by (a) clinical conditions alone; (b) bacteriological findings; (c) legal requirements; (d) all three conditions?

A. All uncomplicated cases of scarlet fever are released at the end of 28 days on clinical conditions alone. If the patient is isolated at home, the period of isolation is terminated on cessation of clinical conditions, but he is not held longer than 56 days. If the case is cared for in the hospital, simple cases are released at the end of 28 days on clinical findings alone. If, however, complications have arisen, bacteriological examinations are made of abnormal discharges, and the patient is released upon two negative examinations for hemolytic streptococci, provided the clinical conditions are otherwise satisfactory.

V

Q. Do you limit activities of patients after release?

A. School children who have had scarlet

fever are not admitted to school until 7 days subsequent to their release from isolation.

VI

Q. What is the duration of quarantine of immediate and susceptible contacts: (a) when the patient is isolated at home with the contacts; (b) when the patient is removed to the hospital or other place; (c) when contacts are removed to the home of adult friends?

A. It is our practice to quarantine susceptible contacts (under 16 years of age who have not had scarlet fever) who are in the same home with a case of scarlet fever as long as the isolation is maintained for the case. If, however, the patient is moved to the hospital, the susceptible contacts are detained at home by a warning sign until 7 days after last exposure. Foodhandlers and teachers, unless they have had scarlet fever, may not resume their usual occupation until 7 days have elapsed, but they may do other work. If within the 7-day period they develop a sore throat and fever, they must immediately stop such work and place themselves under the care of their private physician. When contacts are moved to the home of adult friends, they will be restricted to the premises by a warning card for a period of 7 days, after which, if no symptoms of scarlet fever have appeared, they may return to school or their usual work. By the use of these two methods it is our experience that the incidence of secondary cases among contacts is reduced about 60 per cent.

VII

Q. Do you recommend any prophylactic treatment or provision for contacts?

A. 1. We recommend the removal to the home of adult friends of all young immediate susceptible contacts.

2. If this cannot be done, the removal of the patient to the hospital is a helpful method.

3. The intra-muscular injection of young contacts with 7.5 c.c. of convalescent scarlet fever serum has been found to prevent the development of secondary cases in about 85 per cent, as compared with the incidence where serum was not used.

VIII

Q. Do you recognize scarlet fever carriers? If so, what do you do with them?

A. We recognize scarlet fever carriers only by the appearance of secondary cases. The carrier state usually ceases within a couple of weeks from the release from isolation. Occasionally, several secondary cases are observed occurring at more or less frequent intervals over a period of some months subsequent to release from isolation. Carriers of this kind are hospitalized and their throats treated until negative hemolytic streptococcus cultures

are obtained. Occasionally, the tonsils are removed and the carrier state ceases at once.

IX

Q. What type of restriction is required at the home for isolation or quarantine?

A. If the house is small, the whole house with certain contacts is placarded and thus placed within the isolation area. It frequently happens that the wage earner desires to reside at home. It is usually possible to seal off one room at the house so that he can have access to this room through the window. Several adults can make use of a room of this kind at such a home. In larger homes where there is more than one bathroom with toilet facilities, it may be possible to seal off a portion of it so that in the isolation area will be a bathroom, a sleeping room, provision for cooking and laundry work. Also, it may be desirable to have the food prepared in the kitchen of the home and brought to the entrance of the isolation area. This arrangement is allowed when a registered trained nurse is in charge of the case.*

The remainder of the house is called the Quarantine Area if occupied by other members of the family, of whom only the wage earners may go out and reënter as necessary. Some other homes are large enough so that a part may be sealed off completely from the rest of the home. This provision is allowed whenever possible.

X

Q. What kinds of placards do you use in the control of scarlet fever cases?

A. For the absolute restriction of a case and contacts to a limited area, a red colored placard 6" x 9" is employed which reads as follows:

SCARLET FEVER

No Person Shall Enter or Leave This House Until This Card is Officially Removed.

\$500 Fine for removing or defacing this Notice without Written Authority from the Department of Health.

If removed or defaced without authority,

* In order to secure a supply of qualified private duty nurses who have had special training in the care of communicable diseases, we have recently arranged with the local bureau of nursing to give a special permit card which allows the possessor the privilege of leaving the quarantine area at night and residing elsewhere if she so desires. The qualifications for securing this permit are that she have at least 3 months' training in the care of communicable diseases at our communicable disease hospital or its equivalent, and 3 days' training in field work with the communicable disease nurses of this department. She must be a registered nurse, and must provide suitable testimonials from 2 physicians.

AMERICAN JOURNAL OF PUBLIC HEALTH

occupant of the house must report to the Department of Health, 1300 Beaubien Street, 7th Floor, Telephone Cadillac 2810, otherwise receive the same penalty.

DETROIT DEPARTMENT OF HEALTH

Sometimes a person will be reported who has symptoms suggestive of a case of scarlet fever. There are several diseases for which a similar card can be used. Hence, a warning card has been prepared which has the same size, and a space is left vacant into which the nurse can place a sticker bearing the name of the disease. This warning card reads as follows:

WARNING

A person who has symptoms suggestive of a case of scarlet fever lives here. The danger of catching this disease is not as great as it would be if the person were sick of the disease. However, the movement of this person is restricted to the premises until a definite diagnosis can be made and this card has been removed.

This is for the benefit of the general public. The removal or defacing of this notice is punishable by fine or imprisonment.

DETROIT DEPARTMENT OF HEALTH

Where a portion of a house is occupied by the patient and caretaker, the entrances to the remainder of the house are placarded by a warning sign of the same size which reads as follows:

WARNING

A case of scarlet fever is isolated in a portion of this home. The remainder of the house is a quarantine area which is occupied by other members of the family. Only the immediate members of the household are allowed within this area. Such occupants are of public assembly and public conveyances. Children in this area are prohibited from association with any other persons during the period of this quarantine.

Any information regarding infringement of these restrictions will be appreciated by the Department of Health.

DETROIT DEPARTMENT OF HEALTH

Children who are contacts with a case of scarlet fever are frequently transferred to the home of adult friends. The following warning card is posted for a period of 7 days:

WARNING

A person who has been exposed to scarlet fever lives here. The danger of catching this disease is not as great as it would be if the person were sick of the disease. However, the movement of this person is restricted to the premises until this card has been removed.

This is for the benefit of the general public. The removal or defacing of this notice is punishable by a fine or imprisonment.

DETROIT DEPARTMENT OF HEALTH

XI

Q. Do your regular investigation report blanks indicate name of contacts, possible source of infection, milk supply?
A. Our regular investigation report blanks require all of the above mentioned information.

XII

Q. Have you any special remarks to make regarding the control of scarlet fever?

A. We have not had an outbreak of scarlet fever due to infected milk for the past 15 years, since our milk supply has been pasteurized. About 40 per cent of our cases of scarlet fever are cared for at our community disease hospital. This provision is especially valuable for the care of cases where (a) it is difficult to maintain an isolation; (b) where it will be a financial hardship to the family to have their home in quarantine; and (c) where the serious illness of the patient makes it impracticable to have adequate nursing care at the home.

Occasionally, physicians desiring better medical facilities arrange with the hospital to care for their case in a private room. About 5 per cent of the hospital beds are used in this manner.

It has been known for a long time that the blood serum from persons who have recovered from scarlet fever was a good prophylactic to give young contacts. It has not been possible to arrange for the use of this serum on a wholesale basis. During the last 2 years the department has provided a Serum Clinic which has required the full time of a nurse to secure donors to fill a clinic twice weekly at the rate of \$10 per sample of blood taken. There are 6 to 8 donors present at each clinic. A section of the laboratory has been set aside for the care of the blood received at this clinic. A Kahn test is made of each sample. The blood serum is collected, several samples are pooled, carbolic acid to the extent of 0.4 per cent is added, the serum is put up in bottles of 7.5 c.c. each and also 30 c.c. each, incubated for 1 week and prepared for distribution to physicians.

Outbreaks in institutions or hospitals are cared for in the following manner: Susceptible contacts on the wards and hospital personnel are Dick tested. Those found to be Dick positive are given 7.5 c.c. of convalescent scarlet fever serum. This has been observed to be a very satisfactory method of handling institution outbreaks.

Outbreaks in public schools have been a source of considerable effort. When 2 cases of scarlet fever occur in a school room, all children are inspected by the school nurse, and often by a physician for evidence of sore throat, fever and desquamation. Such cases are excluded at once, and referred to a diagnostician to determine whether or not the patient has scarlet fever. Such children are not allowed to return until given a permit card by this department. During the past 2 years the experiment has been made in 3 schools. When the number of cases at the school was excessive, a request slip was sent home to the parents seeking the privilege of doing a Dick test on their child, and stating that if the case was Dick positive the Department would appreciate an opportunity to give the child convalescent scarlet fever serum. The parents, however, were given the opportunity to have the Dick test made and the serum given by their own family physician if he so advised. Not all parents granted this privilege. These children were used as controls. The experience of these 2 years warrants a continuation of this method on a larger scale.

Experimental work is in progress which was suggested by the work of Loewenstein that toxoid could be absorbed by lanolin, and when rubbed into the skin would stimulate the production of antibodies so that the children would become Schick negative. This principle was applied to scarlet fever. Strong scarlet fever toxin was rubbed up in lanolin in proportions that 1 gm. would contain 10,000 skin test doses. Repeated applications of this inunction to Dick positive children has led to their reactions becoming Dick negative. Work along this line is being actively pursued.

NOTE: All answers refer to practice by the Detroit Department of Health.

The Tragedy with BCG Vaccine at Lübeck—A serious accident involving the use of BCG Vaccine has been reported by the Berlin correspondent of the London *Lancet*. At Lübeck, 246 infants were treated according to the method recommended by Calmette. Of these, 50 became ill with swelling of the inguinal and abdominal glands and other symptoms of tuberculosis. Four-

teen deaths have already occurred. It appears that the original culture was purchased in Paris and that sub-cultures were made in Lübeck. It is declared that the vaccine, as sent from Paris, was in good condition and that some mistake must have been committed in its application. Criticism has been made of the fact that the work was done outside of hospitals and that midwives were instructed to give the vaccine, provided the parents consented. The situation is being thoroughly investigated by the German Health Office.—*Lancet*, 218: 1137 (May 24), 1930.

Public Health Administration—The part that the organized medical profession should play in public health is scarcely second to that of health departments themselves. Local health societies should have public health committees who actively coöperate with and supplement the work of the health officer. Unofficial health agencies must also pattern their activities so as to fit into the official health program. Their work must augment that of the health department without duplication of effort. Medical colleges, state teachers' colleges and the public schools must play an ever increasing rôle in the promotion of health education. The development of facilities for early diagnosis and early treatment by the organized medical profession at a known cost is frankly socialization of the practice of medicine. Such socialization is inevitable. It rests with the profession whether it should seize the initiative and satisfy this demand or stand passively by and be compelled to submit to the process while it is carried out by outsiders.—Allan J. McLaughlin, *Pub. Health Rep.*, 45: 1191 (May 23), 1930.

LABORATORY

C. C. YOUNG, D. P. H.

A RAPID METHOD OF USING THE SABIN SLIDE MICROSCOPIC TEST FOR DETERMINING THE TYPES OF PNEUMOCOCCI *

JESSE G. M. BULLOWA, M. D., AND AUDREY H. SCHUMAN

Department of Health, New York, N. Y.

WITH the separation of additional types of pneumococci by Cooper and her coworkers, which now number 23, and the production of their specific antisera, rapid typing such as can be done with the Sabin method with small amounts of material recovered after injecting a single mouse is of great value to specific therapy.

With the ordinary macroscopic precipitation and agglutination tests at least 0.2 c.c. are necessary for each test. If each of the new types were tested individually, this might require the injection of several mice for each patient, even if sputum were available for the purpose.

With the microscopic slide agglutination test developed by Sabin† in our laboratory, it is now possible to use small amounts of peritoneal exudate such as may be recovered at the end of 3 to 4 hours after the injection of sputum, using the method of Avery and his coworkers. As the best therapy depends upon prompt administration of specific serum, any procedure which limits the amount of material necessary and the number of manipulations prior

to the determination of type is important.

The testing for the presence of a single specific agglutinin in a mixture of several agglutinins is a well known immunological procedure. It is necessary, however, to determine by trial whether the mixing of several agglutinating antisera is an advantageous procedure in view of the possibility that group reactions in the typing sera might reduce the specificity of the reactions for the individual types. For this purpose we divided our 23 types into the following five groups: (A) composed of types 1 through 5; (B) 6 through 10; (C) 11 through 15; (D) 16 through 20; and (E) 21 through 23.

After determining which mixture of antisera agglutinated the peritoneal exudate from the mouse, the specific type was then determined by testing the exudate against the individual type antisera included in the mixture. However, since the types are not distributed evenly in this community, we have thought it an advantage to group them in the following way: Antisera for Types 1, 2 and 3‡ were not pooled so they could be tested individually, but

* From the Littauer Pneumonia Research Fund, New York University, and the Medical Service, Harlem Hospital.

† The "Stained Slide" Microscopic Agglutination Test. Application to: 1. Rapid Typing of Pneumococci—Albert B. Sabin. *Proc. Soc. Exper. Biol. & Med.*, XXVI: 492-494, 1929.

‡ Type 3 was tested individually because of its atypical morphology and agglutination rather than because it occurred frequently. Type 3 organisms have a very large mucoid capsule and accordingly agglutinate very loosely.

the antisera 4 through 8 were mixed, and the mixture was termed group A. Drops of diluted 1, 2, 3, and A were placed separately on one slide. If the pneumococcus being tested did not belong to one of these types, it was tested in the remaining type antisera, arranged in groups B, C, D, and E. Thus a large proportion of our cases, due to the frequency in this community of types 1 through 8, will be diagnosed on the first slide.

According to the strength in agglutinin we have used one of three different dilutions of serum in saline in these tests: (1) 1:25, (2) 1:15 and (3) 1:10.

With the antisera available for these tests all of these three dilutions have been usable but the 1:10 dilution was most satisfactory. This method has been used thirty times and controlled by testing separately for each type. In no case have we failed to determine the type correctly by this short cut method. In addition to the saving of labor and material the early administration of specific therapy is of great advantage. The mixtures given are arbitrary; the groups may be rearranged

to fit the prevalence of the various types in different age groups or in different communities.

A CONVENIENT MIXING CAN FOR USE IN PREPARING DIPHTHERIA TOXIN-ANTITOXIN MIXTURE

GEORGE F. LEONARD, M.D.

New Brunswick, N. J.

THE increasing demand for large quantities of diphtheria toxin-antitoxin mixture made it desirable to prepare large lots in a single mixture. Although the toxin-antitoxin is put through a Berkefeld filter after the mixing, we have always endeavored to keep the material as free from bacteria as possible by using only sterile ingredients and making the mixture in a closed sterile container. Since we were unable to find a suitable mixing can in any of the catalogues from supply houses, we devised

a simple container, which we have found very convenient and durable, for use in preparing toxin-antitoxin mixtures. This container may be used in mixing any sterile preparation.

DESCRIPTION OF CAN

The capacity of the can is 120 liters. This allows ample air space for mixing 100 liters at one time. It is made of copper, lined with tin. It is the shape of an elongated cylinder slightly rounded at each end. The ends are sufficiently

rounded to contain no corners or grooves, which aids in its cleaning; but the bottom is flattened so that it will stand on the floor or a table unaided.

The dimensions of the can, outside measurements, are:

Height, 36".

Width, 19".

Height (straight side), 24".

Manhole (in top for cleaning), 6" diameter.

The weight of the can complete is 35.5 kg.

The can has a heavy iron band around the center on the outside, 2" in width and $\frac{5}{8}$ " in thickness. From this band a short shaft extends on either side of the can. Each of these is 3" long by $1\frac{1}{8}$ " in diameter. The shafts are used in rotating the can in mixing. Just above the iron band, and half-way between the two shafts on either side, is a large handle for lifting.

The manhole cover is threaded into the top of the can and has an asbestos or rubber gasket to prevent leakage. The former is more serviceable, as it is not easily affected by sterilization. This cover contains a flange $1\frac{1}{2}$ " high on top to aid in tightening the lid. In the center of the cover there is a 1" brass stop-cock for the introduction of all materials for mixture. To one side of this stop-cock in the cover is a small stop-cock which is used for an air vent to prevent the liquids from bubbling when being introduced through the larger opening. This small air vent stop-cock is the same as is used to drain automobile gas tanks. At the bottom of the

tank is a $\frac{1}{2}$ " brass stop-cock with the end small enough to go into the mouth of the bottles used in collecting the material.

The can is supported by two wooden horses with a bearing on each to support the shafts on the can. The bearings are made from a piece of iron bar $1\frac{1}{4}$ ", bent to hold the shaft, and bolted to the wooden supports. These bearings could be placed on top of tables, or on brackets supported from a wall. The bearings should be about 34" from the floor to allow free rotation of the can in mixing, and also to allow space for the bottles in emptying the can.

The can is sterilized in the autoclave before use.

MIXING

When all materials have been placed in the can, the manhole cover is made thoroughly tight by means of some wooden object such as a hammer handle or heavy stick, and the stop-cock and air vent are closed. Mixture is made by completely rotating the can on the shafts by means of the handles on the can. It is so well balanced that this is easily done even by one hand.

When mixing is complete the air vent in cover is opened and the material withdrawn from the lower stop-cock directly into sterile bottles. By slightly rotating the can near the end almost the last drop may be removed from the can into the bottles.

The cans were made by George Keller, Copper Works, Brooklyn, N. Y.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Smallpox in the United States and Canada, 1929—Reports from 44 states, the District of Columbia and 8 Canadian provinces show that more cases of smallpox were registered in 1929 than in 1928 or 1927. For both countries combined, there were fewer deaths, and, therefore, a lower case-fatality rate. In Canada, there was much less smallpox than in 1928 or 1927, and the case-fatality rate was low.

In the United States, Illinois reported more cases than any other state, but Louisiana, Maine, Georgia and Texas had notably high case-fatality rates. The country experienced its highest case-fatality rates in areas where there were relatively few cases of smallpox. The only exception to this among the states in 1929 was Texas.

Seldom does a year elapse without affording one or more examples of what happens when smallpox of the more malignant type attacks a community. In outbreaks in Washington, D. C., and Camden, N. J., in 1925, the case-fatality rates were 33.9 per cent and 39.8 per cent, respectively; in 1926 there were 232 deaths in California out of 2,794 cases; and in Arizona there were 6 deaths among 18 persons attacked.

In 1927, a number of cities recorded high case-fatality rates, although, fortunately, the cases themselves were small in number. In Wyandotte, Mich., for example, only 3 smallpox cases were reported in 1927; but all died. In 1929, El Paso, Tex., was the most outstanding example of what happens when virulent smallpox attacks a community. Here there were 11 deaths among 59 cases, corresponding to a case-fatality rate of 18.64 per cent. If this

ratio of deaths to cases had prevailed among the 38,062 persons who had smallpox in 45 American states last year, about 7,100 deaths would have resulted. The same case-fatality rate among 4,251 cases in Illinois would have caused the deaths of nearly 800 persons instead of the 17 which were actually charged to this loathsome disease in that state. In 1922, the case-fatality rate in 43 American states was 2.8 per cent. Had that rate prevailed in 1929, there would have occurred 1,066 deaths in 44 states and the District of Columbia, instead of the 132 that were actually recorded.—*Stat. Bull.*, Met. Life Ins. Co., 11: 6-7 (May), 1930.

Rheumatic Fever in Children—A survey in Rochester, N. Y., showed that the incidence of acute rheumatic infection was from 8 to 10 per cent; acute rheumatic fever involved 2.5 per cent; growing or joint pains were reported in 7.0 per cent; chorea in 0.5 per cent, and heart disease in 2.6 per cent. In this survey it was found that in a group of 20,000 tonsillectomized children between the ages of 5 and 15 years, 399 developed acute rheumatic fever. These children had been tonsillectomized for an average period of 5 years. In a like group of 20,000 untonsillectomized children for the same period, 630 developed acute rheumatic fever. From the same groups it was learned that 1,267 children of the operated group had growing pains, while in the control group 1,530 had the same complaint.

Chorea occurred in 85 children among the operated group and in 75 children not treated. Carditis was found in 450 of tonsillectomized children and in 595

of untreated children. These statistics seem to show that there is a definite lessened incidence of rheumatic infection except chorea in like age groups where tonsils have been removed.

The influence of tonsillectomy in chorea was studied. The incidence among 20,000 tonsillectomized children was 0.4 per cent while among as many untreated children 0.5 per cent. It is interesting to note that the incidence of carditis was 62 per cent among children who developed chorea while the tonsils were in, and 47 per cent among those who developed chorea after tonsillectomy. Removal of tonsils offers very little in the control or prevention of chorea, according to these data.

Among the total 40,000 school children, it was found that 450 whose tonsils had been removed showed evidence of rheumatic heart disease. This represented 2.2 per cent of the entire operated group. Among the 20,000 untonsillectomized children, the incidence of cardiac disease was 2.9 per cent. The lessened incidence of carditis in children whose tonsils had been removed was probably due to lessened incidence of rheumatic infection in general in those children.—A. D. Kaiser, *New York State J. Med.*, 30: 325-330 (Mar. 15), 1930.

Obstetric Costs—An investigation was undertaken in Berkeley, Calif., regarding the physical conditions surrounding maternity and infancy. The sample used was based on the selection of every third birth registered in the city during 1928. A total of 390 obstetric cases was the basis for the investigation and data on cost of obstetric service were obtained for 376 of these cases.

In the series of 390 cases, 144 individual physicians were in attendance, giving an average number of 2.7 confinements per physician. One of the outstanding facts of this study was the

large number of Berkeley mothers confined in hospitals. Of the 390 deliveries, 85.6 per cent occurred in hospitals. During 1928, 83.51 per cent of the total live births occurred in hospitals and 28.9 per cent of these in one hospital. The average number of days spent during confinement in hospitals was 10.

In taking physicians' charges, the amount billed to the patient was used. The average cost per obstetric case was \$92.12, with a median of \$73.87. The modal or most frequent charge was \$50. There was no charge by the physician to 6 patients; the other expenses in these cases totaled \$760.75 or \$126.79 per case. Thirty-one deliveries took place in the county hospital; 17 of the 31 patients paid \$249.80, averaging \$14.69 per case; the other 14 paid nothing for their obstetric care. The sums paid ranged from \$.50 to \$70. Six of the 390 confinements were among industrial policyholders of the Metropolitan Life Insurance Company. The total cost of their obstetric service was \$338.65, averaging \$56.44 per confinement. Only one was confined in a hospital at a total cost of \$103.65. The physicians' charges in these cases were \$50 apiece for 4 and \$35 and \$25 for the other 2.

The total cost of obstetric service to Berkeley mothers, in which at least one item of cost is represented, averaged \$213.75 per case. In half of the cases the charges were \$179.41 or less. The average calculated on the basis of the 390 cases, including patients who did not pay anything, would be reduced to \$206.07. It is safe to state that the total cost of the average obstetric case in Berkeley is somewhere between \$200 and \$215. In exceptional cases and especially those with complications, it may run to \$1,000 or even to \$1,800. The mean cost per case for nursing service was \$116.21 with a median of \$89.—The Cost of Obstetric Service to Berkeley Mothers, R. A. Bolt, *J. A. M. A.*, 94: 1561-1565 (May 17), 1930.

The Suicide Record for 1929—The suicide rate for American cities reached 18 per 100,000 in 1929, the highest figure on record since 1916. The tabulated results of 151 American cities with an estimated population of nearly 38,000,000 showed an increase in the rate from 16.9 in 1928 to 17.5 in 1929. Eighty cities showed an increase over 1928, 56 showed a decrease and in 15 the rate remained stationary. San Diego yielded first place to Sacramento but most of the Pacific Coast cities out-ranked all others in their tendency to suicides. The 7 cities and boroughs with more than 1,000,000 population showed the following rates: Manhattan and the Bronx, 27.8; Los Angeles, 18.1; Detroit, 18.1; Cleveland, 16.8; Philadelphia, 16.3; Chicago, 15.8, and Brooklyn, 14.3.

Of particular interest is the decrease in the suicide rate for Chicago from 18.1 in 1928 to 15.7 in 1929, while the rate for Cincinnati increased from 16.9 to 25.4. The rate for Denver decreased from 27.9 to 20.4, while that for Hartford decreased from 17.4 to 8.7, and New Orleans from 19.6 to 15.4.

The increase over 1928 was by no means as marked as had been expected after the business depression following the stock market collapse. This undoubtedly had a direct bearing on the increase in suicides but when the suicide rates for a period of years are correlated to business failures, there is a fair consistency in the correlation.

In 20 European countries with a population of 240,000,000, there have occurred 253,546 suicides from 1921 to 1927. The annual number has increased from 31,874 during the first year of the period to 40,527 during the last. The European suicide rate has increased from 13.3 per 100,000 in 1921 to 16.8 in 1927. In the U. S. Registration Area the actual number of suicides increased from 52,167 for the period 1919-1923 to 67,888 for the period

1924-1928. The suicide rate for the whole period (1919-1928) increased from a minimum of 10.2 in 1920 to 13.6 during 1928.

The suicide record for Finland dates back to 1751; the rate during 1751-1760 was 1.18 per 100,000, increasing gradually to a rate of 12.5 in 1918, then to 15.1 in 1925, and decreasing to 14.8 in 1926. Sweden's record begins with 1781, starting with a rate of 2.22 in 1781-1820, reaching 10.34 during 1881-1890 and 14.39 during 1921-1925.—F. L. Hoffman, *Spectator*, 124: 3, 18-20, 22 (May 22), 1930.

Airplane Fatalities—While deaths from airplane accidents have never attained much numerical importance in the United States, the latest data suggest that the time may not be far off when they will become a significant cause of death. In the U. S. Death Registration Area in 1928, airplane fatalities numbered 473, as compared with only 214 in 1927; and the death rate increased from 0.2 per 100,000 in 1927 to 0.4 in 1928. In California alone, the number of deaths increased from 27 in 1927 to 96 in 1928, and the death rate from 0.6 to 2.1.

The government statistical records for these accidents date back only to 1919, in which year 156 deaths were reported to the U. S. Bureau of the Census, with a death rate of 0.2 per 100,000. This identical death rate prevailed for 6 of the 9 years from 1919 to 1927. Then, in 1928, came a sharp rise.

The story of the mortality in airplane accidents is very different from that for automobile fatalities. Deaths from this latter cause began to attract the attention of vital statistics bureaus in 1906, when 183 fatalities occurred in the U. S. Registration Area, corresponding to a death rate of 0.4 per 100,000. Immediately, however, a sharp rise was observed. The mortality rate doubled in 2 years and tripled in 3; and in 10 years

it reached 5.9 per 100,000—substantially 15 times as high as in the first year for which records were kept. Obviously this rapid rise in the automobile death rate was due, in large part, to the rapidly increasing number of cars in use. The increase in airplanes, of course, has been a much slower process. Nevertheless, the sudden doubling of the death rate in 1928 suggests that, with more and more planes manufactured and used, the airplane death rate may be about to take a decided upward course.

More deaths from this type of accident occur in California than in any other state. In every year of the period from 1919 to 1928, without exception, the airplane death rate was higher in California than in any other state. A recent report of the U. S. Department of Commerce, nevertheless, accounts for the high mortality in California. This report shows that more than one-sixth of the licensed airplane pilots of the country reside in that state. The actual number is given as 2,244, against 1,153 in New York, 671 in Illinois and 640 in Texas. During the 10-year period, 1919-1928, there were 1,896 airplane deaths in the U. S. Registration Area. Of these, 332 occurred in California, 132 in Ohio, 106 in New York, and 105 in Illinois.

Complete data on airplane fatalities for 1929 are not available at this writing. The National Safety Council has stated the number of deaths in that year, from "civil aviation accidents" alone, as 485. When 91 fatalities in the Army, Navy and Marine Corps Air Services are added to this number, some increase, at least, will be shown over the previous maximum, as recorded for 1928.—*Stat. Bull., Met. Life Ins. Co.*, 11: 3-4 (May), 1930.

Diphtheria Mortality in United States Cities, 1929—A study of diphtheria mortality in 81 cities, all having a population of more than 100,000,

showed a steady decrease in diphtheria death rates throughout the country. The rate for the group as a whole was 7.69, the actual number of deaths, 2,698, being lower than that reported for many years. The northern geographic divisions experienced, for the most part, lower diphtheria death rates in 1929 than in 1928. The rate for the New England group showed a gratifying decrease from 8.59 in 1928 to 7.30 in 1929. The Middle Atlantic cities as a group, although including the largest population, had a lower diphtheria death rate than either the cities of the East North Central or West South Central states, and almost exactly the same rate as the New England and East South Central cities. The rate for the Middle Atlantic cities decreased from 10.80 in 1928 to 7.57 in 1929. The South Atlantic group showed the low average diphtheria rate of 4.70. The Mountain and Pacific cities had the lowest rate, 3.35, of any geographic division in 1929. The rate in the East North Central cities remained about the same, 11.30 in 1929, 11.29 in 1928. The groups of East South Central and West South Central cities both showed increases in 1929 as compared with 1928, the cities of the West South Central area manifesting a rather sharp rise in diphtheria mortality from 6.18 in 1928 to 9.17 in 1929.

Improvement in diphtheria mortality was noteworthy in New Haven, Hartford, Cambridge and Bridgeport. Jersey City, Utica, Rochester and Syracuse showed low 1929 rates. New York City continued its remarkable improvement. Baltimore and Atlanta both made new low records for 1929, 3.9 and 3.8 respectively. Cleveland also made a particularly good record of 3.9. Nashville had in 1929 its lowest diphtheria mortality (4.9) since 1924. The 1929 rates in Duluth, St. Paul and Minneapolis, 0.8, 1.0 and 5.6, respectively, were surprisingly low, considering the

severe climatic conditions which prevail in these cities. Seattle had the third lowest rate in the country, 0.5 in 1929.

Lynn and Fall River showed increased diphtheria mortality in 1929. The rate for Newark remained the same as in 1928, 20.0, and was the second highest in the country. Norfolk, which showed an increase, had the relatively high rate of 6.5 in 1929. Detroit showed an increase from 16.2 to 21.8, the highest 1929 rate in the country. Louisville, Birmingham and Memphis showed increases in diphtheria mortality in 1929 compared with 1928. Dallas, San Antonio, Chicago, Paterson, Springfield, Mass., and Camden were in the group with the highest diphtheria death rates in the country in 1929.—*Diphtheria Mortality in Large Cities of the United States in 1929, J. A. M. A.*, 94: 1838–1841 (June 7), 1930.

Vital Statistics for Spain—During 1929, there were 653,571 births in

Spain, giving a birth rate of 28.9 per 1,000 population compared with 29.7 in 1928. The excess of births over deaths was 246,150 against 253,068 in 1928, indicating that, at the present time, the population of Spain is increasing by about a quarter of a million per year. Infant mortality was 123 per 1,000 births in 1929 and 125 in 1928.

General mortality declined from 18.4 in 1928 to 18.0 in 1929. Decreases over 1928 were shown for tuberculosis all forms, 136.4 per 100,000 population in 1929 against 139.0; and cerebral hemorrhage and softening, 124.8 and 130.6. All communicable diseases showed decreased mortality rates. Heart disease increased from 163.4 per 100,000 population in 1928 to 168.9 in 1929; influenza, 15.4 to 24.3; pneumonia, 39.5 to 43.0; and other respiratory diseases, 147.2 to 160.0. Puerperal septicemia showed a decrease from 22.0 per 1,000 live births in 1928 to 20.0 in 1929.—*Pub. Health Rep.*, 45: 582–583 (Mar. 14), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Overnight Camps—Inspection of 170 overnight camps in New Hampshire revealed camps of many types, varying greatly in size and accommodation. An estimate places the number of accommodations at these camps for one night at 6,393. Included in the inspections, which were made under the general laws in regard to nuisances, there being no regulations as yet on definite standards for overnight camps, were water supply, toilet facilities, and general camp cleanliness. If dining rooms were attached, as was the case in 56 camps, the equipment for caring for the food was inspected.

The water supply in general was very good. In some instances suggestions were made for improvement. Of those that were analyzed only one was found dangerously polluted. In regard to toilet facilities, 17 camps had installed chemical toilets, 76 had provided flush toilets with proper sewage disposal, and the remainder, pit privies. Where necessary, need for improvement was called to the manager's attention. Managers, in general, welcomed inspection and suggestions.

The estimated investment of the bungalow villages is about \$150,000. Many of these have their own laundries, run-

ning water, electric lights, shower baths and modern conveniences. It is felt by the State Board of Health that no danger or menace exists in the tourist camp for the traveler.—Anon., *Health*, New Hampshire State Board of Health, Sept., 1929, pp. 2–5. (From *Public Health Engineering Abstracts*, Feb. 22, 1930. Abstr. F. O. A. Almquist.)

Progress in Water Purification—

The results of previous investigations on the problems of softening, recarbonation, flocculation and increased use of chlorine are described. The question of the pollution and self-purification of rivers is discussed. River pollution may be estimated by the oxygen demand. An electrical process for following the course of covered mains and a new American rustless iron pipe are described. Improvement in aeration technic has led to the removal of noxious gases, a considerable reduction in the amount of chlorine required, and better flocculation. The increasing use of sodium silicate and lime for the reduction of lead corrosion is dealt with.

Researches on the significance of pH values in softening and experiments with natural zeolite are mentioned. In connection with flocculation, the results obtained by the production of artificial turbidity for combating strong algal growths in raw water tanks are especially noticeable. The filter rate was considerably lengthened and, in the case of a residual turbidity of 100 mg. per liter, heavy flocs, which carried away further quantities of organisms, formed in the settling tank.

A good flocculation is said to be obtained by a new type of mixing plant, the operation of which depends on the gradual reduction of the water velocity to quite a small value. Useful experience with superchlorination has been obtained in Toronto; the greatest amount of chlorine used was 3 mg. per liter.—N. J. Howard, *Surveyor*, 75: 203, 1929;

Wass. u. Abwass., 26: 173, 1929. (From Papers of Water Pollution Research Board, England.)

Chloramines in the Disinfection of Water—

Various investigations of the formation of monochloramine, by the addition of ammonia or ammonium salts to calcium hypochlorite or chlorine, and its use in the disinfection of water are discussed. Details and tables of results are given of experiments carried out to determine whether the addition of ammonia or its compounds increased the germicidal efficiency of chlorine and, if so, under what conditions the efficiency was greatest. When the water was clear and of low organic content, the addition of ammonia with chlorine retarded the disinfection, except when the chlorine was in great excess of the ammonia. When small quantities of chlorine were used the final disinfection was less than with chlorine alone. In turbid waters of high organic content, the addition of ammonia increased the germicidal velocity of the chlorine.

There was no apparent loss of free or saline ammonia. The most effective ratios of chlorine to ammonia were not definitely determined, but in turbid waters of high organic content satisfactory results were obtained with the ratios of $\text{Cl}_2 : \text{NH}_3$ of 1 : 2 and 1 : 3.

The chlorine-ammonia method is recommended for the treatment of raw unfiltered waters, especially if long periods of detention after chlorination are available. References to literature are given.—J. J. Hinman and K. C. Beeson, *J. Am. Water Works A.*, 21: 1705, 1929. (From Papers of Water Pollution Research Board, England.)

Dechlorination of Water by Activated Carbon—

The author describes a series of experiments carried out to obtain practical knowledge of the working of an activated carbon filter for the dechlorination of superchlorinated wa-

ter. The first series of experiments described was of short duration carried out with fresh filter material. It was found that the percentage decrease in chlorine content for a given length of filter run and an equal speed of flow was independent of the original concentration of the chlorine. Increased speed necessitated increased length of filter. Different activated carbons (AKT II, III and IV and Urbain HAS 18) are classified by the length of filter run required to reduce the chlorine content of a water by one-half at a speed of 1 cm. per second and a method of calculating the size of filter required is described.

In further experiments continuing over a considerable time it was found that the life of the filter material without regeneration varied with the composition of the water. Regeneration investigations showed that treatment of the carbon either with a hot soda solution in the filter or by removing from the filter and heating to a dull red heat was successful.

"Fatigue" in the filter appeared to be due to the formation of a gelatinous membrane which was peptonized by the hot alkali, or contracted by heating. With a hard carbon the loss of material in regeneration should not be serious.

Experiments on a practical scale in superchlorination and dechlorination were made with a traveling "Dabeg" plant to test the possibility of a supply of Elbe water for Aussig, and on the very favorable results the decision to use Elbe water as a supplementary supply was based.

In the course of discussion the author stated that his calculations of the size of filter required held good for most natural waters but the presence of ammonia, by the formation of chloramine, lengthened the time necessary for dechlorination.—H. Pick, *Vom Wasser, Ver. deutscher Chemiker*, Berlin, 3: 71, 1929. (From Papers of Water Pollution Research Board, England.)

Odor Control at the Macon Sewage Plant—The Macon, Mo., sewage plant is located close to a residential district and serves a population of 3,500. It consists of coarse bar screen, Imhoff tank, sludge drying bed and sprinkling filter. For several years odor difficulties have arisen. The authors carried out an experiment on chlorination as a means of odor control during 4 consecutive days in midsummer. Hourly observations were made of the rate of sewage flow, applied and residual chlorine, hydrogen sulphide and odor at the filters and at a distance of 400 ft. from the filters. The treatment prevented odors and at a maximum dosage cost \$4.65 per m. g. The dosage depended on the time of the day and varied from 3.9 to 10.9 p.p.m. To avoid odors, a maximum of 1.5 p.p.m. of volatile hydrogen sulphide should not be exceeded.—W. S. Johnson and H. Bosch, *Pub. Works*, 60: 400, 1929.

Living Tubercle Bacilli in a Septic Tank Effluent—Inoculation experiments on guinea pigs showed that chlorinated septic tank effluent did not cause tuberculosis, while an untreated septic tank effluent aroused the disease in inoculated animals.

The tubercle bacillus therefore withstands not only acids, alkalies, and digestion processes, but also the septic processes in a septic tank.—S. L. Cumins, D. Davies, and C. M. Acland, *Tubercle*, 10: 310, 1929; *Zentralbl. f. d. ges. Hyg.*, 20: 409, 1929. (From Papers of Water Pollution Research Board, England.)

Results of Tests on Sewage Sludge—This bulletin gives an account of the objects, methods, and results of tests made at the experimental sewage testing plant of the Engineering Experiment Station of the University of Illinois. The plant itself, the sewage, and the method of supplying sewage to the

plant are described. Sludge digestion in deep and shallow Imhoff tanks was studied.

Sludge from a deep tank drained and dried better than that from a shallow tank and was of better quality. The shallow tank also accumulated more sludge, digestion apparently being slower, and had the disadvantage that sludge had frequently to be removed.

Tests on the effect of the addition of moisture to sludge on drying beds showed that well moistened sludge did not form a hard surface, and was more cracked and broken than unmoistened sludge. In almost every case, but especially with well digested sludges, the more moistened sludges showed a lower final moisture content and a greater volume reduction than less moistened sludges. It appears that covering sludge beds must therefore be ineffective in assisting drying and may even handicap the process by lack of ventilation.

Sludge frozen on the beds gave on thawing a very easily drained sludge, fine grained and easily pulverizable. The water content was less than with unfrozen sludge but the per cent reduction in volume was also less. It therefore appears advisable to draw sludge from tanks during winter months and also to remove frozen or semi-frozen sludge from beds to make room for more. In this condition it is easily transported and may be allowed to thaw and disintegrate at the point of final deposition. Activated sludge also drains well after freezing.

Efforts were made to find an expression for the relation between the factors affecting sedimentation and the per cent removal of suspended particles. Observations were made with coal and sand as sediment and with dilute and concentrated sewage. It was not found possible to formulate an expression for a relation between the different factors, but from tests in which all possible factors were controlled an empirical for-

mula was devised, expressing the relation between the different variables. With low concentrations, however, the per cent reduction of settling solids was found to be quite erratic.

Experiments on gas production in ordinary Imhoff tanks showed that the amount increased with the amount of sludge accumulating in the tank and with increase in temperature. The average quantity produced was about 0.3 cu. ft. per head per day. It is not practicable to heat Imhoff digestion chambers above the temperature of the incoming sewage because of the heat lost in the flow of sewage and disturbance of sedimentation by convection currents. Separate sludge digestion experiments carried out in a shallow Imhoff tank showed that it was advantageous to carry out digestion in two stages, the first in an upper compartment separated from the lower by a slot trapped against reverse flow of gas. The size and operation of such a tank are described. The rate of gas production was greatly increased by heating from 10° C. to 26° C.—H. E. Babbitt and H. E. Schlenz, *Univ. of Illinois Eng. Exper. Sta. Bull. No. 198*, 1929. (From Papers of Water Pollution Research Board, England.)

2,300 Tons of Pollution Afloat in Manhattan Atmosphere—An investigation by Professor H. H. Sheldon indicates that approximately 2,300 tons of foreign matter float in the Manhattan atmosphere. Professor Sheldon used a rather unique method in making the tests by measuring the amount of dust and dirt caught by the air conditioning systems in Broadway motion picture theaters. These systems, in addition to circulating the air, wash and humidify—or dehumidify—it. In this process, which is accomplished by water sprays, 96 per cent of the foreign particles in the atmosphere is removed. The test revealed that the 341,000,000 cubic feet

of air passing through the tanks contained $11\frac{1}{4}$ cubic feet of dust and dirt. This ratio applied to the city's atmosphere gives 35,160 cubic feet, or 2,300 tons, as the amount of foreign particles in the air. Samples analyzed indicate that 65 per cent of these particles was unconsumed carbon, 15 per cent stone dust and mineral matter, and 20 per cent germs.—Anon., *Am. City*, 41, 2: 167 (Aug.), 1929. (From *Public Health Engineering Abstracts*, Feb. 22, 1930. Abstr. J. B. Harrington.)

The Effect of an Alternating Electric Current on Tubercle Bacilli in Milk—This article includes a description of experiments conducted by the author in treating raw milk artificially infected with tubercle bacilli in commercial apparatus designed to heat the milk almost momentarily to about 160° F. by passing a 220 volt, 60 cycle alternating current through it and cooling it as quickly as possible. The heating unit consists of 2 water cooled flat carbons 24" long and held 3" apart by hard rubber spacers. This forms a rectangular chamber 3" by 4" in cross-section through which the milk is pumped. The electrical input is constant and the temperature to which milk is heated is controlled by regulating the rate of flow by means of a hand controlled valve and by automatically varying the current in the field of the motor driving the centrifugal milk pump through the medium of a vapor tension bulb located in the milk line beyond the carbons. The milk is heated regeneratively from about 60° F. to 120° F. and then electrically from 120° F. to 150° F., 155° F., or 160° F., the temperatures used in the experiments.

Three experiments were run, one in July, 1924, one in November, 1925, and one in June, 1926. In the first experiment 50 gal. of milk inoculated with a large quantity of a culture of bovine tubercle bacilli was treated at 160° F., then 50 gal. similarly inoculated at 155° F., and then another 50 gal. of inoculated milk were treated at 150° F. Samples were collected at various points at the beginning and end of each run and injected into guinea pigs. The second and third experiments were run in the same way except that 100 gal. of milk were used for each run and human as well as bovine types of tubercle bacilli were added to the milk. The author reports that all the guinea pigs injected with inoculated raw milk and with milk preheated to 120° F. died from generalized tuberculosis or showed it at necropsy. Some of the guinea pigs after injections with milk treated at 150° F. showed either generalized or localized tuberculosis. The guinea pigs given injections with the samples of milk treated at 155° F. and 160° F. remained healthy and increased in weight.

The author states that "The electrical conductivity method of treating milk effectively destroyed tubercle bacilli with which milk had been artificially inoculated." He does not, however, say whether he believes the results to be due to some electrical effect in addition to heat, as the title might imply, or whether the same results might be expected by the application in some other form of the same degree of heat for the same length of time.—Charles M. Carpenter, *J. Infect. Dis.*, 44, 5: 347-356 (May), 1929. (From *Public Health Engineering Abstracts*, March 1, 1930. Abstr. Walter D. Tiedeman.)

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Report of Industrial Hygiene Committee: State and Provincial Health Authorities of North America, 1930—A questionnaire was sent to the various state and provincial departments of health to determine the extent of industrial hygiene activities. It was found that, even in those states and provinces where the law requires reporting of occupational diseases, the large majority receive few or no reports of cases. In the states and provinces which compensate for occupational diseases under the schedule form, practically only those occupational diseases are reported which are compensated. In those states and provinces where all occupational diseases are compensated, the number of cases reported is woefully incomplete in the majority of instances.

Four departments of health have bureaus or divisions of industrial hygiene; 1 a bureau of housing and industrial hygiene; and 1 a bureau of industrial hygiene and factory inspection; 5 departments of health have a specific appropriation for industrial hygiene purposes; 4 departments have a laboratory for industrial hygiene; and 5 use laboratory facilities of the department of health or consultants.

With few exceptions, comparatively little work is being done by the health agencies in this country. Connecticut has prepared a working classification of industries and of hazardous materials, processes, and conditions. The industries are divided into about 100 groups, and the hazardous materials, processes, and conditions into about 70. This system provides an organization of our information on occupational disease exposures in the various industries in the states.

The control of occupational disease requires more than plant inspection. Before effective work can be done in this direction, it is neces-

sary that scientific methods, physical and chemical procedures be applied to the problem. For many materials, the minimal amount which will affect the health (threshold dose) is known, and it is only by utilization of these procedures that we can know definitely whether the exposure is below that limit. This necessitates a laboratory and technical assistance.

The minimum set-up for a division or department of occupational disease is a physician with a broad knowledge of occupational diseases and industrial environment, a chemical engineer, trained in industrial procedures, capable of making the necessary field determinations of gases, dusts, fumes or other materials or conditions that may affect health, a clerk and a laboratory. The laboratory must be specially equipped to make these determinations. This division should:

1. Secure and investigate reports of occupational diseases.

2. Make necessary field studies of workroom environment including special determinations of gases, dusts, fumes and toxic materials; air velocity, temperature, humidity, general ventilation, illumination, or any conditions or processes thought to be affecting health.

3. Provide a source of information for physicians, industry, or any agency interested in the cause, treatment, and prevention of occupational disease.

The committee found a certain amount of important work performed during the past year such as studies in sandblasting and silicosis, radium painting, lead poisoning, benzol and other poisonings, ventilation and illumination. Several states have adopted codes governing spray painting.

It is recommended that every effort should be made to increase the reporting of occupational diseases: that general practitioners should be further impressed with the necessity of securing complete occupational histories of their patients; that more time should be devoted in the medical school to the ef-

fect of occupation upon health; that surveys should be made of those industries in which potential hazards are known to exist in order to clear up the conditions causing occupational diseases; and that special laboratory facilities and technical personnel are required in this field.

There accompanies the report a list of hazardous substances, processes and conditions for coding occupational diseases, devised by the Connecticut State Department of Health. Likewise, a chart showing by states and provinces whether or not reports of occupational diseases are required; whether received by the health or labor departments or both; whether a reporting form is required; the number of cases reported annually for the 5-year period ending in 1929; whether or not a bureau of industrial hygiene exists and the personnel maintained; the appropriations made; laboratory provisions; and whether or not important legislation upon the subject exists and the same in regard to important regulations for 1929-1930.—Mimeographed Report distributed by the Connecticut State Department of Health, Hartford, June 10, 1930.

I. Classified Index of Occupations. II. Alphabetical Index of Occupations—These two volumes prepared by the U. S. Bureau of The Census for the 15th Census of the United States, 1930, have now become available for distribution. The Indexes are based upon the occupational designations returned at the previous three censuses with certain supplements.

The *Classified Index* which sells for 50 cents comprises 205 pages. It includes the subject of "repeater" occupations with their symbols, a grouping by industries with proper symbols, a brief industry index with symbols, and then an extensive alphabetical arrangement under the various industrial classifications also with symbols. The In-

dex enables one to find the various occupations which may exist in the given industries, trades and callings.

The *Alphabetical Index* is a volume of 527 pages, repeating in its fore part the industrial classification and industry index of the former volume, but devoted almost entirely to an arrangement of occupations in alphabetical order, a second column showing the industry and a third column the symbol to be used designating the given occupation.

The price of this volume is \$1.00.

Complete explanations for use accompany each volume.

The Indexes will be used by the Bureau of The Census in classifying the occupations returned on the population schedules at the 15th Census, and in classifying the occupations returned on birth and death certificates.

The Indexes were prepared by Dr. Alba M. Edwards, expert on occupations, under the general supervision of Dr. Leon E. Truesdell, chief statistician for population.

[Abstractor's comment: These volumes, arranged for standardization of terminology in occupations, should prove invaluable to all manner of offices, bureaus and persons dealing with occupations.]—U. S. Bureau of The Census, Washington, D. C.

Household Mechanical Refrigeration—This is Report 2 of the Committee on Poisonous Gases of the American Medical Association and has special reference to the toxicity of refrigerants used. The Report was drafted for the committee by Dr. Carey P. McCord, Cincinnati, O. There is a discussion of the systems of household mechanical refrigeration, a list of 44 substances that may be used as refrigerating mediums, and a statement of the objections to both the single and the multiple systems, the latter being potentially a far greater source of harm than the former.

The fundamental properties of an

ideal refrigerant are listed, such as non-inflammability, non-explosiveness, non-toxicity, absence of odor and of visible fumes, operation at low pressure, lack of corrosion, absence of deleterious effects on foods, etc. A second table shows the relative toxic properties for six of the commoner refrigerants used and there is a discussion of carbon dioxide, dry ice (solid carbon dioxide), silica gel, methane, ammonia, sulphur dioxide, ethyl chloride, and methyl chloride, with a considerable discussion of the literature on intoxication, particularly of methyl chloride.

Industrial poisoning from ammonia, sulphur dioxide, and methyl chloride, and the matter of the introduction of warning agents, refrigeration codes and moral obligations are discussed.

In part summary of the committee's position are these findings: Household refrigeration is a factor for good in the promotion of public health and economic living. For this reason no action or attitude is warranted that would tend to hamper the manufacture and use of safe refrigerators. Greater precautions, however, are called for. The introduction of warning agents *per se* (toxic or non-toxic) is regarded as not commendable. "This practice does not adequately provide protection for all classes of persons, including infants, locked-in children, the insane, the sick, or the aged." Codes governing the safe manipulation of refrigerants should attain uniformity through joint efforts under such auspices as the U. S. Public Health Service.

Every manufacturer of a product that may injure the user has a responsibility to try out and test all substances with harmful properties. The use of toxic substances without adequate safeguarding or warning should lead to penalties. "It is no longer to be tolerated that manufacturers procure information as to toxic substances through the deaths and illnesses of consumers." In connection

with the recent deaths from methyl chloride, sufficient medical and chemical data were already available to have prompted safeguardings. Unfinished and unpublished work indicates that a practical refrigerant is now promised which is sufficiently free from toxic properties. As with foods and drugs, a similar federal law and governmental supervision are needed in regard to possibly harmful substances.—Committee Report, A. M. A., J. A. M. A., 94, 23: 1832-1838 (June 7), 1930.

Refrigeration—It is estimated that 60 per cent of the families in the United States do not have proper refrigerating facilities in their homes. The methods of refrigeration involve either the use of ice or the evaporation of some highly volatile chemical substance which abstracts heat.

Among the essentials no harmful effects should result from the refrigerant used, either upon the food or by leakage into the rooms. A mechanical refrigeration system consists essentially of two parts—an evaporator and a compressor with adjuncts—and such systems are usually constructed as single units or so-called multiple systems (the latter in apartment houses, etc.).

The most common refrigerants used are sulphur dioxide and methyl chloride, but domestic use is also made of ammonia, carbon dioxide, and ethyl chloride. There are advantages and disadvantages to all of these, particularly in relation to their toxic qualities or, as in the case of carbon dioxide, to the excessive pressure—700 to 900 lb.—under which they are used. (The properties of sulphur dioxide and methyl chloride are briefly summarized.)

Leaks in mechanical refrigerating systems are common. Investigations made by the Department of Health during recent months disclosed 190 leaks; of these, 152 were in multiple systems, and 38 in single units. Leaks were

found of nearly all of the common gases used, sulphur dioxide being the most frequent, with 82 leaks; and methyl chloride the next, with 77. Leaks in multiple systems are much more common than is ordinarily supposed, and on this account a legal code of specifications is essential. Ten deaths have been definitely attributed to the escape of poisonous refrigerant gases into places of human habitation.

Leaks of sulphur dioxide are readily detected from the characteristic pungent odor and suffocating effect, but the gas may be tested for with ammonia fumes, when a white cloud is formed at once. In the case of methyl chloride there is no simple way for the householder to know whether a leak has occurred, so that the Department of Health should be notified at once when a leak is suspected. Dr. Julius Stieglitz of the University of Chicago recommends a test apparatus consisting of an alcohol lamp with a fine copper mesh screen around the flame. In the presence of methyl chloride, the flame turns a greenish color.

A number of precautionary measures are described.—Arnold H. Kegel, *Chicago's Health*, 24, 23: 126-132 (June 10), 1930.

Diagnosis of Silicosis—In a disputed case of silicosis in which the post-mortem examination when held showed that the man had died of silicosis, the Home Secretary (Mr. Clynes) replied that the diagnosis during the workman's lifetime had been confused with anthracosis, making it one of peculiar difficulty, and that the case afforded a very good illustration of the need for improved medical arrangements by the setting up of an expert medical board, and such steps are now being undertaken for the Workman's Compensation (Silicosis) Bill.—Parliamentary Intelligence, *Lancet*, 5572: 1320 (June 14), 1930.

Sixth International Congress for Accident Surgery and Labor Medicine—This Congress is to be held in Geneva, Switzerland, August, 1931, the last one being held in Budapest, September, 1928. The principal questions to be discussed are the following:

I. Slow Results and Evolution of Traumatic Wounds of the Spine

II. Traumatism of Blood-Vessels (Arteritis and Thrombophlebitis)

III. Cutaneous Infections in Relation to Labor Accidents

IV. The Previous State in the Consequences of Labor Accidents

In addition to these topics, others of particular interest in the field of industrial medicine will be scheduled. Authors will also be permitted to submit special subjects.

An exposition of radiographs, photographs, and mouldings, etc., will be held. Those wishing to exhibit should apply to Dr. Jentzer, Geneva, rue de l'Université 8.

The President of the Organization Committee is Professor Julliard, Geneva, and the General Secretary, Dr. Yersin, 3, rue de la Monnaie, 3, Geneva.

The American members of the Permanent International Committee are: Dr. Fred H. Albee, New York, N. Y., and E. R. Hayhurst, Columbus, O. The official delegates from the United States to the last Congress (Budapest), in addition to the two above named, were Dr. Francis D. Patterson, Philadelphia, Pa., Dr. Francis D. Donoghue, Boston, Mass., and Dr. D. J. Prather, U. S. Public Health Service. The American Committee for the Sixth Congress is now being organized.

Organic Fluorides as Refrigerants—Irrespective of otherwise satisfactory engineering and thermodynamic properties, all refrigerating agents previously used have been either inflammable, toxic, or both.

This paper covers a new class of re-

frigerating agents—organic substances containing fluorine. Some of them are surprisingly non-toxic. Dichlorodifluoro methane is less toxic than carbon dioxide, as non-inflammable as carbon tetrachloride, and very satisfactory from every other standpoint. Its toxicity has been studied by the U. S. Bureau of Mines and the results are included. (See Abstract, *A. J. P. H.*, 20, 7: 780 (July), 1930.)

A method of correlating the properties of this class of substances is presented, and the method of manufacture of dichloro-difluoro methane is described. The article is accompanied by two charts and one illustration.—Thomas Midgley, Jr., and Albert L. Henne, *Indust. & Eng. Chem.*, 22: 542 (May), 1930.

A Study of Silicosis in Rock Drillers—The author describes the findings of the committee organized by the New York Tuberculosis and Health Association to make a study of the hazards of rock drilling in Manhattan which was carried out by the association in connection with the Vanderbilt Clinic

of Columbia University and the Metropolitan Life Insurance Company, during 1928 (see *J. Indust. Hyg.*, Feb., 1929). Following this study official and non-official agencies held a conference designed to lessen the dust hazard. Tests of a dust collection system were made which showed an efficiency such as to reduce 423,900,000 particles to 23,000 per cu. ft. minimum. The U. S. Public Health Service has adopted as a permissible limit 10,000,000 particles under $10\ \mu$ per cu. ft. Thus it is not necessary to remove 100 per cent of the dust.

A very valuable discussion follows the above paper by those present at the Buffalo, 1929, meeting of the International Association of Industrial Accident Boards and Commissions, part of which devolved around the Ontario Silicosis Law—which provides that there must be an exposure to silica for 5 years before a workman is entitled to compensation, during which time the exposure must be in Ontario.—A. J. Lanza, *Proceedings of the 16th Annual Meeting of the Internat. Assn. Indust. Accident Boards and Commissions*, Bull. No. 511, U. S. Bur. Labor Statistics, Apr., 1930, pp. 40–47.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Blacktongue-Preventive Value of Lard, Salt Pork, Dried Green Peas, and Canned Haddock—In a former experiment (Abstract, this JOURNAL, 28: 1183 (Sept.), 1928), the blacktongue-preventive action of 16 selected foodstuffs was reported. The study here reported was made on pork lard, salt pork, dried green peas, and canned haddock. The same general procedure was followed as in the previous experiments.

Details are given as to feeding experiments, symptoms, etc. Results indicate that lard and salt pork are poor sources of the blacktongue preventive. Canned haddock contains the blacktongue-preventive factor and when used in large proportions the clinical manifestations of blacktongue are prevented. Dried green peas contain the blacktongue preventive, but in small amounts.

Fifty or more of the test animals on lard, salt pork and haddock diets showed

postmortem evidence of fatty degeneration of the liver.—Joseph Goldberger, G. A. Wheeler, L. M. Rogers, and W. H. Sebrell, *Pub. Health Rep.*, 45: 1297 (June 6), 1930.

Vitamin A and Carotene. II. The Vitamin A Activity of Red Palm Oil Carotene. III. The Absence of Vitamin D from Carotene. IV. The Effect of Various Dietary Modifications upon the Vitamin A Activity of Carotene—Carotene from various sources has shown vitamin A activity in the hands of certain investigators, but other pigments such as xanthophyll, lycopin, and the like, have been reported deficient in growth promoting powers. The unsaponifiable fraction of red palm oil has been studied and a method given for extraction of the carotene. Colorimetric determinations were made of the unsaponifiable matter in the isolated pigment in oil solutions both for the natural yellow and the color evolved with antimony trichloride.

In the biological tests on rats growth curves show that 0.01 mg. of the pigment was sufficient to restore growth in 2 rats compared to 0.2 mg. of the unsaponifiable concentrate paralleling the activities of carotene in unsaponifiable matter derived from carrots.

Other investigators have indicated that carotene does not possess antirachitic power. In confirming this young rats were placed on rachitogenic diets and various doses of carotene in peanut oil were administered daily for 35 days when they were autopsied and their bones examined. Results showed that carotene would not prevent rickets at a level of 100 times the minimal dose for vitamin A.

To determine the effect of dietary modification in carotene feeding two experiments were run; one group of rats received a basal diet of 15 per cent peanut oil and in the second group this was substituted by rice starch. A few of

the rats received vitamin D as irradiated ergosterol. At cessation of growth carotene was administered at the 0.01 mg. level dissolved in peanut oil for 1 group and in paraffin for the group on the fat-free diet. Carotene restored growth in all cases although it was least effective where paraffin was the vehicle.

In the second experiment one group received the fat diet with vitamin D and the second group the fat-free diet without vitamin D, and at the cessation of growth carotene was administered at the same 0.01 mg. level. Similar responses in both groups indicate the activity of carotene in the absence of fat in the basal diet.—Thomas Moore, *Biochem. J.*, 23: 1267, 1929.

Bacteria of the Upper Respiratory Tract and Middle Ear of Albino Rats Deprived of Vitamin A—An investigation is reported in which a study was made of the relation of avitaminosis (A type) to bacterial invasion of the nasal cavities and middle ear. A bacteriological study of the nasal cavities and middle ear in 79 albino rats is presented for 4 groups: normal stock rats, vitamin-A-deficient controls, rats on a vitamin-A-free ration which developed xerophthalmia, and those on a like diet which did not develop the disease. Four types of organisms pathogenic to rabbits were isolated. These are classified as *Staphylococcus aureus*, *B. coli*, *M. catarrhalis* A, and *chromogen* 6, the last two being gram-negative cocci. From observations it was quite apparent that the pyogenic gram-negative cocci, especially *chromogen* 6, are encountered more frequently in the animals which show the most severe symptoms of vitamin A deficiency. It is indicated that these organisms gain a pathogenic hold during the depressed state of their host resulting from vitamin A deficiency. Some evidence is given that cod liver oil protects against bacterial invasion of the nasal cavities and middle ear.—R. G.

Turner, Dorothy E. Anderson, and E. R. Loew, *J. Infect. Dis.*, 46: 328 (Apr.), 1930.

Brucella Agglutinins in the Blood and Milk of Cows—Observations over a period of years are reported on the correlation of specific agglutinins for *Brucella* species in the blood and milk of cows. Two herds of 91 and 81 animals respectively served as the basis for these observations. In both herds it was observed that the disagreements between the blood and the milk agglutinins consisted largely of negative reactions in milk serum when the blood serum of the same animal was positive.

It is concluded by the authors that a negative agglutination test with milk serum is not a reliable indication of the *Brucella* agglutinin content of the blood of the same animal. Agglutination with the milk serum detected from 47 to 68 per cent of the cows in two *Brucella* infected herds whose blood serum reacted. These observations tend to confirm the generally accepted limitations of the milk serum test for *Brucella* agglutinins in the diagnosis of this infection in cattle.—Robert Graham and Frank Thorp, *J. Infect. Dis.*, 46: 260 (Mar.), 1930.

Beef Extract as a Source of Vitamin G—A series of experiments are reported for the purpose of determining the relative amounts of growth promoting vitamin G (pellagra-preventive) in commercial beef extract obtained from different manufacturers. Relative amounts of vitamin G were estimated by feeding tests with young albino rats using samples of beef extract from five different sources.

Fresh lean beef was examined for comparison. It was found that an intake level of 7.5 per cent of moisture-free beef extract from each of four establishments furnished sufficient vitamin G for good to excellent growth in rats. The same percentage of beef extract

from the other establishment promoted only fair growth. In these experiments the average daily intake of moisture-free beef extract was approximately 0.80 gm. for males and 0.65 gm. for females. Twenty per cent of dried lean beef furnished sufficient vitamin G for fair growth and 25 per cent enough for excellent growth in rats.

The average daily intake of 25 per cent dried beef amounted to 2.7 gm. for male and 2.2 gm. for female tests. One pound of moisture-free extract appeared to contain approximately the same amount of vitamin G as 3.4 pounds of dried beef. Therefore, if the commercial products are compared, 1 lb. of concentrated beef extract contained approximately the same amount of vitamin G as 11 lb. of fresh lean beef.—Ralph Hoagland and George C. Snider, *J. Agri. Res.*, 40: 977 (June), 1930.

The Oxalic Acid Content of Vegetables Used as Greens—This study was made to compare the oxalic acid content of spinach with that of other leafy vegetables used as greens. The vegetables used were obtained in the open market during the summer of 1928 and 1929. Three different lots of spinach bought at different times were analyzed.

One sample of New Zealand spinach was used and two varieties of mustard were used. In addition, beet tops, turnip tops, kale and dandelion leaves were used. After cleaning and removing roots and stems, the remaining portion was washed, the surplus water dried off, and the fresh weight determined, after which they were dried to constant weight at a temperature of 80° to 85° C. The dried vegetables were then finally pulverized.

A modification of the Bau method for determining total oxalic acid content of coffee, tea, spices and vegetables (*Z. Nahr. Genussm.*, 40: 50-66, 1920) was used.

Tables are given showing the results of this experiment. The oxalic content of spinach, while varying in different samples, was much higher than is generally supposed, ranging from 0.486 to 0.692 per cent. Beet greens contained an amount equivalent or slightly higher than spinach and New Zealand spinach was found to contain considerably more. Dandelion greens, kale, turnip greens and mustard greens contain no oxalic acid. In view of the unexpectedly high percentages of oxalic acid in spinach it is worthy of note that large quantities of this vegetable are consumed apparently without adverse effects on health.—Alice E. Ryder, *J. Home Econ.*, 22: 309 (Apr.), 1930.

Cows Infected with Streptococcus Epidemicus (Davis)—Over a period of 4 years the authors have investigated 17 cows which were found to be shedding in their milk *Streptococcus epidemicus* (Davis). The milk from 2 of the cows was associated with an epidemic of septic sore throat among consumers. The other 15 cows were giving milk which was mixed with a considerable quantity of other milk and used as food. No clinical symptoms of epidemicus infection were produced among the consumers of the milk from these cows. In none of these cases have the authors been able to establish any relation between a streptococcus throat infection in those who handle the cows. It was concluded that in most cases there is a probability that the cows were infected before they were brought to the farms where the infections were discovered.

Eight of these cows were found in certified herds of approximately 1,200 cows which have been regularly tested at monthly intervals. The other 7 were accidentally discovered in small herds.

As a result of their investigations, the authors indicate that the cows infected with *Streptococcus epidemicus* are rather generally and widely distributed

and that this streptococcus undoubtedly occurs quite generally and frequently in milk used for direct consumption as well as that used for cheese and butter making without producing disease. The infection of cattle with this human type of streptococcus apparently begins as a mild disease which may become very severe or apparently continue a mild course.

There is a tendency for the infected portions of the udder to lose their milk secreting functions. In the group of mild cases to which most of the cows involved in this investigation belong, there is little or no change from the normal in either the udder or the milk, although *Streptococcus epidemicus* may be shed in large numbers.

Of the 13 cows in which the extent of the infection was determined by the investigators, 7 cows, 53 per cent, were infected in only one quarter, 4 cows, 31 per cent, were infected in two quarters, 2 cows, 16 per cent, were infected in three quarters, although the infection in the different quarters did not always occur simultaneously. The strains of *Streptococcus epidemicus* which were isolated are apparently all virulent and are identical with those strains isolated from epidemics from either man or cow.—W. D. Frost, R. C. Thomas, Mildred Gumm, and F. B. Hadley, *J. Infect. Dis.*, 46: 240 (Mar.), 1930.

Vitamin C Content of Three Samples of Japan Green Tea—The present work is a continuation of that previously reported (Abstract, this JOURNAL, 19, 11: 1262 (Nov.), 1929). Since only one sample was used in the first experiment and no attempt was made to determine whether the tannin might have been responsible for the results, it was thought advisable to make a more complete study. One strong tea infusion was made with enough water added to bring the final volume up to 100 c.c. instead of 125 c.c. In all other

and a watch or warning letter sent home to the parents.

2. Educate the community to avoid contacts, and teach sanitation and personal hygiene. The public health nurse is one of the front line troops—she should provide explicit information to the mother regarding immunization, and she should give only *approved*, given 6 times a week. Tea infusion is given of the changes in weight and scurvy symptoms in guinea pigs.

Of the animals given the weaker infusion of tea, 3 survived the full 90-day test period, one died on the 83d day and all showed mild symptoms of scurvy at autopsy. The animals fed the strong infusion lived to the 80th and 81st day and scurvy symptoms were slightly more severe than those of the first group.

time she should be carefully examined. The entrance physical examination is not sufficient, or periodic examination is not enough for finding tuberculosis. Eight out of every 100 are missed with the regular physical examination. In every case where the tea infusion was fed in conjunction with cabbage the animals grew well and showed no signs of scurvy. It was concluded that the symptoms observed in the guinea pigs receiving tea infusion as the only test food must have been due to the lack of vitamin C and not to a poisonous effect of tannin.—Hazel E. Munsell and Charlotte H. Miller, *J. Home Econ.*, 22: 314 (Apr.), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Canada Has This Problem, Too—
The present opportunities for service and development in the public health nursing field are not generally enough recognized by the large group of nurses graduating every year from the nursing schools. Dr. May Burgess, Director of the Committee on the Grading of Nursing Schools in the United States, says that of the nurses who have been graduated less than a year about 7 per cent hold public health positions, 24 per cent hold institutional positions, and the other 69 per cent are in the field of private duty.

Recent graduates drift naturally into private duty nursing or institutional nursing because they are more familiar with these types, because they usually require no further preparation, and because the nurses want to become self

supporting quickly. It takes an adventurous type of girl to look forward to going out into a community alone to do public health work, and her nursing school experience has not given her much chance to develop initiative.

The nursing superintendent and her assistants cannot always give much time to individual guidance during the nurses' training, but they should know that there are certain times in the year when many private duty nurses are unemployed, whereas a qualified public health nurse is practically sure of steady employment. More continuous effort is needed to give information on public health nursing to nurses in training. If an affiliation with a good public health nursing organization is not possible, workers from public health nursing agencies could be brought in at times to interpret their work to the senior nurses, the hospital administrative staffs and alumnae associations.

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

health nursing in Canada are not getting enough well qualified applicants; during the year only 64 nurses graduated, and several times this number could have been placed. This means that nurses less qualified must be gotten to fill the positions that are opening.

The economic side presents difficulties, but any girl who has a real desire to become a qualified public health nurse usually gets there. There is great need of scholarships, however, for a public health nursing course does take more money.

Often too much is expected of the university public health nursing course. Every nurse graduating from one cannot be an expert in every type of public health nursing. All she has gained is an insight into the possibility of each, and before she can really do effective work she should have practical experience under nursing supervision. Medical supervision is not enough.

Two ways of meeting this situation (too little field work experience) would be either through the universities withholding certificates until a definite period of field work has been accomplished, or having the organization proposing to employ a nurse accept her on an instructive basis and at a lower salary for a period of time until she is better able to assume additional responsibility. With the demand for their services this safeguard has not been taken sufficiently into consideration.

—Elizabeth L. Smellie, *The Problem of Securing Recruits for the Public Health Nursing Field*, *Canad. Pub. Health J.*, XXI, 5: 240 (May), 1930.

Of Interest to School Nurses—
The greatest need today is to perfect school health programs. Health education is at the crossroads. What we need more than propaganda and moti-

courses or study that are graded; (2) training of classroom teachers; (3) training courses at normal schools; (4) summer school classes; (5) health score cards that are used and get results; (6) tests and measurements; (7) educational objectives linked with projects that result in achievement; (8) recognition of health education as an integral part of the curriculum.

To achieve a better health education program in the schools, the following criterions are essential: (1) adequate facilities, (2) sufficient time allotment, (3) trained personnel, (4) recognition and credit, and (5) better programs.—James Edward Rogers, *What Can the Volunteer Agency Do to Assist State Departments of Education to Obtain Adequate Supervision of Health Training?* Abstracts of papers presented at 26th Annual Meeting of the National Tuberculosis Association, Memphis, May 7-10.

Heard at the Biennial Nurses' Convention at Milwaukee in June.

Communicable Disease Control—Every nurse is a communicable disease nurse. Her first duty is to know the local laws. She has no responsibility to diagnose, but if she cannot give her suspicion of a diagnosis it is a sad reflection on her intelligence.

Ways to check the spread of communicable disease:

1. Through the schools. The health department should have a physical inventory of every individual in the community.

(a) The teacher should list the diseases of each child and get some idea of how far an outbreak may progress.

(b) Non-immune children should be sent home if there is an outbreak of communicable disease, isolated for a required number of days,

and a watch or warning letter sent home to the parents.

2. Educate the community to avoid contacts, and teach sanitation and personal hygiene. The public health nurse is one of the front line troops—she should provide explicit information to the mother regarding immunization, and she should give only *approved*, not debatable information.

—John J. Sippy, M.D., District Health Officer, San Joaquin Local Health District, Stockton, Calif., Communicable Disease Control.

Tuberculosis—In a study made in the hospital nursing schools in the Twin Cities 20 per cent of the pupil nurses reacted positively to the tuberculin test on entering, and 100 per cent reacted on graduating. In a similar study made in the ordinary schools 2 per cent of the entering students showed a positive reaction to the tuberculin test, and only 30 per cent of the graduates had a positive reaction. Of the 543 nurses receiving aid through the Relief Fund of the American Nurses' Association 258 have tuberculosis.

How do student nurses become infected?

Not through overcrowded living conditions. This in itself cannot cause tuberculosis; and not through overwork if there is a proper amount of rest.

The nurse does not report when ill or her illness is considered minor. At this

time she should be carefully examined. The entrance physical examination is not sufficient, or periodic examination is not enough for finding tuberculosis. Eight out of every 100 are missed with the regular physical examination. ~~There~~ ^{They} ~~should be an X-ray and a tuberculin test.~~

One explanation of the high incidence of tuberculosis among nurses:

They are exposed to tuberculous patients. General hospitals accept tuberculosis patients daily though they are supposedly not admitted. The nurse can accomplish much and control the situation if all cases are regarded and treated as communicable disease problems.

The following rules would help the situation:

1. Every pupil nurse should have a routine X-ray and tuberculin test.
2. Every patient should have an X-ray and a tuberculin test. Only 1 case in 500 would then be missed.
3. Every hospital should reserve space for its tuberculous patients.
4. Nurses should be trained to care for tuberculous patients—there would then be better qualified public health nurses.

—J. A. Myers, M.D., University of Minnesota, Minneapolis, Minn., Tuberculosis. (Extracts from the notebook of Henrietta Landau, R.N.)

Recruiting

THE attention given in nursing magazines to recruiting students suggests that professional health work might claim more of the best of our college students if some one would lead the way in promotion effort to that end.

In "This and That in Nursing Edu-

cation and Practice," by E. E. Cortright, a group of working ideas are offered for taking "the necessary measures to produce an intelligent public opinion on the facts in training schools as they are operated today."—*Am. J. Nurs.*, May, 1930.

E. G. R.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

A Public Health Nurse Informs Her Public—The *Monthly Bulletin*, Indiana State Board of Health (May, 1930), tells how a committee of five conducted a county public speaking campaign. In conclusion, the article states:

The results of this tour have been far-reaching. News stories, bulletin board material, posters, public group meetings, suggestions and general follow-up visits made by the nurse—all receive far more intelligent attention now that the public has been systematically informed—in advance. Then, too, the eleven evening trips helped the five members of the committee become better acquainted with each other and with each other's common problems. A splendid foundation has thus been laid for a lasting spirit of understanding and coöperation between the school, agricultural, tuberculosis, medical and nursing groups and the entire country.

"Telling Marie Over the Telephone" (*Red Cross*—*Courier*, Washington, D. C., June 16, 1930. *Free*)—A monologue was given at an award of certificates to a home hygiene class:

On the speaker's stand stood a telephone receiver, and when the signal bell rang an honor student answered it to talk to a "friend." . . . "Hello! Marie! How are you? I'm fine. Well, Marie, I am glad you called me. I want to tell you about my Red Cross Home Hygiene class. You know I have told you several times special things I have learned in this class. Now I am through with the lessons and the American Red Cross is giving me a certificate—it's so pretty, with a Red Cross on it—and it means that I am better able to keep the family well, or to help them get well if they do get sick, than I was before. Goodness, Marie! I have learned the most things. I can make a nice, comfortable bed. . . .

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Health Education Pioneer—The recent appointment of President Livingston Farrand of Cornell University as head of a special commission to study the possibility of increasing public health effectiveness in New York State reminds one that President Farrand was a pioneer in recognizing and encouraging the popular methods of health education of today. Under his administration of the National Tuberculosis Association there was carried on the first widespread service of public health information to the newspapers of the country.

Publicity Exhibits at Fort Worth—Space limits and hanging facilities make it uncertain how much or what kinds of publicity material it will be possible to display at Education-Publicity Headquarters at the Annual Meeting of the American Public Health Association.

Unusual forms and sizes are difficult to display. Groups of small items should be placed in a portfolio or scrapbook and not mounted on large cards. Three dimension material is desirable, but it is especially important that arrangements for space should be made in advance. An interesting display sent from New York to Minneapolis arrived without a plan or instructions. It could not be shown and was difficult to re-ship.

The only way in which a good exhibit can be planned is to select from available material what is best adapted to space and circumstances; so will you please write well in advance to the Editor of this department telling what you have to show which might help other health workers with their educational

publicity. You will receive a reply about October 1 stating when and where to send the exhibit, if there is space for it.

A Proposition for National and State Agencies—It is not possible through the resources of the Public Health Education Section to compile nearly so many collections of educational material as would be useful at the A. P. H. A. Annual Meetings. Workers are eager to examine collections of material from their specialized fields in addition to those collections which illustrate good practice in the preparation of different forms of publicity whatever may be the subject matter.

Could we have the active coöperation of national and state health groups?

Suppose the American Heart Association should make up a portfolio (or several of them) of its own newest and best educational and publicity material—together with that issued by state and local groups?

And then if other nationals would do likewise in their specialized fields?

The collections could include news releases, newspaper clippings, radio talks, bulletins or house organs, folders, etc., and of course lists of available educational material, material about the organizations and the services they offer.

Probably such collections should be displayed at the several headquarters of the nationals at Fort Worth—and afterwards be available at the home office of each national. A classified group of portfolios shown at the recent convention of the nursing organizations aroused so much interest that five additional sets are being prepared for loan to local agencies.

A somewhat different plan might be carried out by a state department or association. This would be a portfolio, or several of them, made up of the educational-publicity material of all types

issued by departments and associations throughout the state. We hope that Texas and several other states will prepare such displays for Fort Worth.

If you like the idea help it along by urging it upon your national and state agencies.

A memorandum describing how to make up portfolios will be supplied by the editor of this department.

Social Hygiene in a Y. M. C. A.—“An adequate program of sex-education information that will give the secretarial staff an up-to-date scientific knowledge of how to deal with this subject” was requested by a Y. M. C. A. The reply from the American Social Hygiene Association is supplemented by suggestions for dealing with groups reached by the Y. M. C. A.—“From a Young Men’s Christian Association.” *J. Social Hyg.*, 370 7th Ave., New York, N. Y., May, 1930, pp. 303–309. Something to be brought to the attention of your local Y. M. C. A. One working idea could be carried out by any interested organization:

Coöperate with the city libraries:

In choosing and securing for library circulation enough of the best sex education literature, and advertising its availability, in the community, in suitable ways.

In eliminating from circulation all out-of-date and undesirable material. This second item is fully as important as the first. Most libraries still carry many publications that are crude, misleading stuff. Perhaps two-thirds of the popular sex literature on the market at the present time is undesirable; hence intelligent discrimination is urgent.

Remember the Guest Editor—When you read this the year-round editor will be east of the Atlantic. For consideration in writing copy for this department to appear in the October issue please send your specimens and ideas—not later than August 25—to Dr. H. E. Kleinschmidt, National Tuberculosis Association, 370 Seventh Avenue, New York, N. Y.

Again the Annual Meeting!—Again it is a privilege to invite those concerned with any phase of educational publicity to use to the utmost the resources of the Public Health Education Section of the A. P. H. A. in connection with the annual meeting in October.

Here is hoping that the "Big Boss" will surprise you by proposing that "for the good of the order" you should begin planning to go to Fort Worth in October!

You might prepare the way by making up a list of the questions you would like to have answered and the topics you would like to discuss with fellow workers.

Last October at Minneapolis we had a group of portfolios containing educational and publicity materials which were classified under the following topics: cancer, children—schools, diphtheria, health examinations, heart disease, diet and weight, rural sanitation, summer warnings and advice, winter warnings and advice.

If you will send your 1929–1930 popular educational material on these topics it will be added to the display at Fort Worth. Please use this full address: Fort Worth Portfolios, Evart G. Routzahn, 130 East 22d Street, New York, N. Y.

The Public Health Worker's Vacation—Paul Sartorus, discussing "The Advertising Man's Best Vacation," quotes Abraham Lincoln:

"For myself, I feel—though the tax on my time is heavy—that no hours of my day are better employed than those which bring me again within the direct contact and atmosphere of the average of our whole people." After describing his "promiscuous receptions" which occurred twice a week, Lincoln continued, "I call these receptions my *public-opinion* baths! . . . and the effect, as a whole, is renovating and invigorating to my perceptions of responsibility and duty."

Sartorus tells of various advertising men who use vacation to get new con-

tacts with people and things. The flivver and tourists' camps did the job for one man. Another man goes into a new section of the country every year. The four chief men in one agency each go into a new section annually. One man spent the summer on a mid-western farm—and has done better work on farm paper copy ever since. When one does not wish to get far away from people, to get somewhere among "average" people and into some new life setting is urged for the one who is to plan or to write advertising (or health) copy. *Advertising and Selling*, 9 East 38th Street, New York, N. Y., June 25, 1930. 15 cents.

What? When? Who? Why?—What questions would you like to have answered? What problems solved? What methods worked out? What topics in health education-publicity should be talked over in print or in conventions?

The editor of this department is making a collection of questions and topics—big and little—easy and hard—which might be answered in some meeting, or be the topic for a meeting, or be handled in this department.

Send what you have now. Send others at any time.

What About Billboards?—Health agencies and churches seem to be the chief non-commercial users of outdoor billboards. Notwithstanding the vigorous propaganda against billboards from several quarters, but little direct opposition has heretofore been directed specifically to the church and health people for their outdoor posting, but the E. D. C. forces have met enough criticism this year to lead health workers to a consideration of the problem.

What are the objections to billboards? Are the objections general, or are they qualified by certain conditions? In so far as the objections are valid, must

they prohibit health workers from the use of billboards? Are billboards a useful medium for popular health education? What are the principles upon which health agencies should base their discussions for or against billboards?

What ideas have you on the subject?

HEALTH "BEST SELLERS"

Child Health Day brought much further use of *The Child's Bill of Rights*, by President Hoover. This is probably the most frequently published and most widely distributed health propaganda in this country.

The pamphlet on *Consumption*, by Dr. A. Knopf, published in that period before the Great War in which some recent writers have urged that little or no health education was known, is probably the health publication issued in more languages and more countries than any other.

But the genuine "Best Seller" among health books is *Diet and Health*, by the late Dr. Lulu Hunt Peters. For about 2 years this book was among the 10 "best sellers" in non-fiction titles, frequently topping the list. It was displaced only with the coming of *The Story of Philosophy*, and its kindred group of phenomenal non-fiction sellers.

A lightness of touch in writing, with a rare perception of the points of view of the lay reader and his difficulties in carrying out health and medical instructions, drew a great audience for Dr. Peters, whose recent death was a serious loss to popular health education.

BELIEVE IT OR NOT

The house organ of a tuberculosis sanatorium carried on its cover page a picture in color—a hospital interne rescuing a nude woman from the clasp of an energetic skeleton! Possibly an inspiration to the professional audience to which much of the publication is addressed—but who knows?

A well-written pamphlet, making an

impressive plea for the support of a state association, carries an application blank without the address to which it should be sent. On the back appear the individual addresses of all members of the executive committee but no hint as to which one should receive the application. When the signer hesitates, he is lost—usually.

EPITAPH

Here lies James,
Though feeling poorly—
He paid no doctor
Prematurely.
Also—post mortem
Diagnosis
Showed arterio-
Sclerosis.
How much more pleasant
My narration
Had James a
Health examination!—*Jean Pinney.*

A REQUEST

Copies of posters and other material, as well as suggestions helpful in preparing a health exhibition, will be appreciated by Dr. Samuel de Madrid, Professor in the Popular University at La Boca, Buenos Aires. Address: Corrientes 915, I. Buenos Aires, Argentine Republic.

HONORABLE MENTION

To Hygienic Institute (Department of Health), La Salle, Ill.: for annual report with full table of contents.

To Division of Infant and Child Hygiene, Indiana State Board of Health: for table of contents in annual report (labeled "Index" and placed at the back instead of in the front).

NEW

Pittsburgh's Health, Department of Public Health, Pittsburgh.

EDUCATIONAL MATERIAL

A new list of their "best sellers" has been issued by New York State Committee on Mental Hygiene, 105 East 22d Street, New York, N. Y.

A new list of pamphlet publications has been issued by American Social Hygiene Association, 370 Seventh Avenue, New York, N. Y.

The Canadian Dental Council, 170 St. George Street, Toronto, "through the generosity of the Canadian Life Insurance Officers Association," has issued two booklets with illustrations in color: "At the Gate" and "The Joy of Living." Also two reprints: "Romance in Dentistry" and "Back of the Last Frontier." *Free.*

Committee on the Costs of Medical Care, 910 Seventeenth Street, N. W., Washington, D. C., issues numerous pamphlets. *Write.*

"Health Wanted," Tuberculosis Committee, A. I. C. P., 105 East 22d Street, New York, N. Y., 8 pages; novel cover ideas; good layout of pictures on pages; few words. *4 cents.*

Improved Sanitation in Milk Production, by Department of Agriculture. Revised. Superintendent of Documents, Washington, D. C. *5 cents.*

"The Present Status of Maternal and Infant Hygiene in the United States," by Lee K. Frankel, Metropolitan Life Insurance Company, New York, N. Y. *Free.*

"Rickets—A Tale of a Gust of Wind." League of Red Cross Societies, 2, Avenue Velasquez, Paris, France. 5 mimeographed pages. *Free.*

Sanitation of Schools—Suggestions for Teachers. Superintendent of Documents, Washington, D. C. *5 cents.*

"Swimming Pools and Other Public Bathing Places." Wallace and Tiernan Company, Box 178, Newark, N. J. Reprinted from *American Journal of Public Health*. *Free.*

SCHOOLS—CHILDREN

"Visual Aids for Health Lessons" is a 6-page catalogue of material offered for local school use by the Health Education Department, Public Health Cen-

ter, Oakland, Calif. Includes projectors, models, charts, posters, films, and film slides.

A series on "Lesson Planning in Health Education" began in the April issue of *Mind and Body*, New Ulm, Minn.

TIMELY TOPICS

The College of Agriculture, Cornell University, Ithaca, N. Y., issues a poison ivy bulletin which may aid in writing copy for use in other states. *Free.*

"A Noble and Loyal Friend" is the caption under a photograph of a dog on the cover page—inside is copy on "Rabies."—*Chicago's Health*, Department of Health. April 15, 1930.

Fundamentals of Camping, by Mary Alden Hopkins. *High School Service*. American Red Cross, Washington, D. C. May, 1930. *15 cents.* Material for house organ or news release. Includes simple statement on use of chloride of lime for purifying water.

Camp and outing standards can be furthered through publicity. A "Report Blank for Overnight Hikes, Weekend Camps and Gypsy Trips," obtained free from Girl Scouts (670 Lexington Avenue, New York, N. Y.), could be the basis of copy on the subject. The Girl Scouts also issue a "Troop Camp Report Blank" which includes questions of health significance under "Camp Site," "Housing," "Sanitary Arrangements" and "Hygiene, First Aid and Safety."

CONTEST—STORIES

The Journal of the Outdoor Life, 370 Seventh Avenue, New York, N. Y., offers prizes of \$20.00, \$10.00 and \$5.00 for the 6 best stories, and \$3.00 each for other stories it may use. "All stories must be in prose and deal in some way with tuberculosis although this need not be the outstanding theme." Closes September 1, 1930. *Write for details.*

BOOKS AND REPORTS

Practical Psychology and Psychiatry

—By C. B. Burr, M.D. (6th ed.)

Philadelphia: Davis, 1930. 378 pp.

Price, \$2.75.

Back in 1898 nurses in institutions for the mentally sick were not so fortunate as their present-day sisters in receiving training and enlightenment with regard to the nature and treatment of mental disease. Few if any nurses' training schools offered satisfactory courses in this subject and most of the hospitals for mental diseases were required to undertake the training in the fundamentals of psychiatry themselves if their nurses were to have any systematized knowledge about it. To be sure, there were several textbooks on mental disease nursing in those days but there was great room for improvement in them. To meet this need, Dr. C. B. Burr, then an assistant physician on the staff of the Pontiac State Hospital for Mental Diseases in Pontiac, Mich., decided to write a textbook that would facilitate the training of nurses in this particular subject.

Dr. Burr's textbook was entitled "Practical Psychology and Psychiatry" and some indication of its unusual value and popularity is found in the fact that this book has run through five editions since 1898.

Now in 1930 comes a new and revised sixth edition which is considerably enlarged over previous editions and which contains much new material. The mental nurse and attendant will extract a great deal of very solid value from this book for it is concisely written, free from frills, and gives unusually specific instructions for dealing with the 101 different problems that arise in the bedside or institutional nursing of the patients of this sort. In the section de-

voted to the definition and causes of insanity, Dr. Burr has called upon the remarkably wide and extensive experiences of his own knowledge of this work as gained by more than 45 years of experience in psychiatry. He has made free and liberal use of illustrative case material and he has also been generous in interspersing the technical material of the book with numerous of his own inimitable philosophies of life.

Faithfully read, it is believed that the nurse or attendant will find this book helpful in caring for those men and women in institutions who are undergoing "a prolonged departure from their normal standard of thinking, feeling and acting."

GEORGE K. PRATT

Bio-Dynamics: The Battle for Youth

—By Boris Sokoloff, M.D., Sc.D.,

Ph.D. New York: Covici, Friede,

1930. 293 pp. Price, \$3.00.

The author's conception, though by no means new, is, as presented, likely to interest those who desire aid in speculating on the limitedness of the cycle of life of man. It was not written for biologists or specialists. Though not a treatise on longevity, it maintains the hypothesis of immortality and develops Metchnikoff's theory of senility and disease. That "death is better than old age" is the basic idea presented, and the aim of the treatise "is a qualitative betterment of life from the biological point of view, an amelioration and conservation of energy."

The relation of regenerative capacity and potential immortality met with where there is slight differentiation (as in the infusoria) is contrasted with the almost nonexistent regenerative capacity, the evolution of death, and the potential immortality preserved only in

the sex cells found in highly differentiated organisms (such as man). The latter possess glands which appear to be the centers of dynamic and organizing energy in the organism. The imperfect present-day knowledge of the functioning of the endocrine glands permits the author merely to indicate the trend of experimentation. That these glands are powerful agents in promoting individualization, in preserving health, etc., he demonstrates.

Senility is defined and explained as "the result of disruption and degeneration of the endocrine gland system."

Bio-dynamics is defined as "the science of the creative dynamic forces of the organism." The final analysis of life remains a question.

The book is interestingly written and fairly well documented, but we can recommend it only to those who already have knowledge of the subjects treated.

ESTHER W. STEARN

Your Nose, Throat and Ears—By L. W. Oaks, M.D., and H. G. Merrill, M.D. *New York: Appleton, 1929.* 167 pp. Price, \$1.50.

This book is written for lay people in simple and understandable language and will undoubtedly have its appeal.

The facts disclosed may enlighten the average person to such an extent that he will mend his unhygienic ways and thereby benefit.

Based upon an understanding of anatomy and physiology to be obtained from its perusal it is to be hoped that the layman will be inspired to obtain medical care early—and even more important, avoid the pitfalls of quackery.

ALEC N. THOMSON

New Uses for Capital—By Robert S. Field. *Philadelphia: Winston, 1930.* 136 pp. Price, \$1.50.

In the words of the author, this little volume is an effort to promote a wider appreciation of the financial basis of our

national progress. The essay is divided into three parts: capital and how it is invested; new objectives for investment (life and health, security and peace of mind, leisure and recreation); and methods of approach (philanthropy and taxation). Much of the basic material seems to have been assembled from reliable sources familiar to public health workers. There is relatively little new either in the approach or subject content. Most of the compilation was done while the author was engaged in graduate study.

IRA V. HISCOCK

Undulant Fever and Contagious Abortion—By L. C. Bulmer, B.S., N.D.D. (Eng.). *Birmingham, Ala.: Technical Service Bureau, 1930.* 66 pp. Price, \$1.60.

This monograph summarizes much of the existing information concerning undulant fever in humans and contagious abortion in animals, and discusses the relationship of one to the other from the standpoint of transmission through meat and milk products. The material furnished affords information of interest to health officers, laboratory and agricultural workers. A useful list of chronological events—from the time Hippocrates described a protracted fever in 400 B.C., which Castellani and Chalmers believe was what is now known as undulant fever, through the reports of 1929 A.D.—is one feature. There is also a summary of comments from authoritative sources and a bibliography of 135 references.

IRA V. HISCOCK

Gesundheitswesen und Wohlfahrts-pflege im Deutschen Reiche—Von Prof. Dr. med. Bernhard Möllers. (2d ed.) *Berlin: Urban & Schwarzenberg, 1930.* 634 pp. Price, 38 marks, bound.

The second edition of this much esteemed treatise on public health and welfare work in Germany will be welcomed in view of the post-war develop-

ments in this field in that country. These have been so far reaching as to require a very considerable expansion of and extensive modifications in the text of the first edition published in 1923. These affect, largely because of new legislation and regulations, the fields of the prevention of venereal diseases, child welfare, food control, care of sick and dependent classes, and social insurance. Statistics compiled last year in Germany indicate a falling off of nearly 50 per cent in the incidence of venereal diseases since the last survey in 1919.

Additions include new vital statistics resulting from stabilization following post-war aberrations, and sections on supervision of water supplies, public baths, sewage disposal, the hygiene of industry and of prisons, cancer campaigns, rheumatoid complexes, and sport and gymnastics. The discussions of tuberculosis among prisoners, and on preparations of salvarsan and on the Wassermann reaction, trypanosomiasis, apprentice and investment insurance, are given an enlarged treatment. The regulations and legislation in public health matters in Germany, among German speaking peoples, and public health movements in the League of Nations are reviewed in the third section of the book.

On account of the inclusiveness and the up-to-dateness of this edition it will be of unusual value to American workers in public health in presenting current practice in a European nation which is well advanced in this field.

C. A. KOFOID

Public Health Aspects of Dental Decay in Children—By Raymond Franzen, Ph.D. A. C. H. A., 1930.
121 pp. Price, Cloth \$1.25, Paper \$1.00.

It is with great regret that so much unusual mental ability as the author possesses has been allowed to err for

lack of proper guidance. No one individual can be expected to master all branches of science, but before undertaking a subject requiring considerable highly specialized knowledge, the researcher should either familiarize himself with the basic scientific facts or obtain competent coworkers to furnish a knowledge of the field being studied. Any medically trained person should know that the correlation between a carious condition of teeth in horizontal relation to each other would be higher than between those in vertical or diagonal relation. A knowledge of elementary dental embryology teaches the reasons for this without a research.

The author after his exhaustive study "leans toward an organic or anatomic explanation of the sources of (dental) decay." Who does not? He seems to ignore the relation of environment to the development of teeth within the jaws.

Again, why should "treatment accorded to deciduous teeth have a protective influence upon permanent teeth"? Of course, corrections influence favorably the progress of decay in the teeth treated.

Dr. Franzen's conclusions on page 39 are correct. He admits the same are not new to the dental profession; then why so important to school administrators? A school board or superintendent would certainly employ a person trained in dentistry before undertaking a dental program for school children. The observations and conclusions of Chapter V on correlation of stain and tartar with dental caries are correct and in accord with accepted thought.

The application of his conclusions in Chapter VI are logical and interesting in that they confirm clinical observations with mathematical accuracy, which is of value although many practical workers in the field will question the wisdom of conducting such researches without adequate dental knowledge being made available as a guide for the

worker who is to apply the technics of modern research. We fail to see that this research has added anything to our knowledge that will help the public health official with the problems of dental disease among school children.

HARRIS R. C. WILSON

Social Control of the Mentally Deficient—By Stanley P. Davies, Ph.D. New York: Crowell, 1930. 408 pp. 12 ill. Price, \$3.00.

Once every so often—but unhappily not often enough—a truly monumental book flashes across the horizon of our times. This is one of those volumes, although the reviewer is convinced that this book will not flash transiently, but will remain for many years a classic in its field.

Here is a portrayal of the development of both popular and scientific attitudes with regard to feeble-mindedness from the earliest recognition of this condition down to the present day. Dr. Davies has wielded a facile pen in giving us a picture that is as fascinating as it is accurate. Do not suppose, however, that specificity has been sacrificed to the generalities that ordinarily are required by facile writing. On the contrary the book is replete with dates, statistics and other factual data that make it a valuable source-book for students of mental deficiency.

The author, in the 18 chapters that comprise this book, discusses such things as changing concepts of heredity, newer aspects of behavior, sterilization, segregation, the mentally deficient in the social order, and similar topics of interest. Each chapter is concluded with a useful bibliography, and Dr. Davies consistently gives chapter and verse to his references.

Perhaps the chief value of this book is found in the ability of the author to give us a step by step picture of the position of the mentally defective in the community. In so doing, he has given

us also a picture in longitudinal section of the growth and changes in social thinking. This has been accomplished throughout with a commendable and highly unusual objectivity.

It is difficult, as one reads this book, to draw conclusions as to what may be the author's personal views, and since he has not set out to prove anything, but only to record, this lack of emotional bias gives the book a noteworthy standing.

Health officers, nurses, physicians, social workers, students of psychology, and others, cannot afford to ignore *Social Control of the Mentally Deficient*. Dr. Frankwood E. Williams has written a foreword in which he states: "It is a book that is of more value for the student of the social aspects of mental deficiency than any other book I know."

GEORGE K. PRATT

1930 Municipal Index—Published by American City Magazine Corporation, 443 Fourth Avenue, New York, N. Y. 855 pp. Price, \$5.00.

The 1930 Municipal Index is the seventh edition of this yearbook prepared especially for city, town and county officials, state highway engineers, and all others interested in public improvement activities.

For the convenience of those using this handy reference book there are an alphabetical list of subjects, an index of manufactures, and consultants using the pages for advertising, and a classified list of products and services.

The subject matter is divided into 18 major sections, and sandwiched in between sections are advertisements which in a measure relate to the activities discussed in the preceding pages.

Sections in the 1930 Municipal Index which are of direct or indirect interest to public health workers deal with:

Administration, Planning, Finance, Law, Health and Welfare (Section 2)

Progress in Civic Center Development (Section 3)

Water-Supply and Purification (Section 7)

Swimming Pools and Other Public Bathing Places (Section 8)

Sewers, Sewerage and Sewage Disposal (Section 10)

Garbage, Ash and Rubbish Collection and Disposal (Section 11)

Parks and Playgrounds (Section 14)

National, State and Local Organizations (Section 17)

City Managers, Mayors, City Engineers, and Water Works Superintendents (Section 18)

Among the items touching the field of public health which are of special interest should be mentioned the suggested list of health books for city hall libraries; a bibliography on water-supply and purification; standards for public bathing beaches and wading pools; and statistics on garbage collection and disposal in 557 cities over 4,500 population.

The list of national organizations serving municipalities and local civic groups, arranged alphabetically, and providing the name of the executive officer and the address, will be welcomed by busy administrators.

A new feature of the *1930 Municipal Index* is the tabulation of city managers, mayors, city engineers, and water works superintendents in cities over 10,000 population, showing the annual salary of each. It is to be regretted that similar data for health officers in these cities are not included. Perhaps a suggestion on this might be made to the editors for the 1931 edition. A. W. FRAAS

A Survey of the Law Concerning Dead Human Bodies—By George H. Weinmann, LL.B. Bulletin No. 73. National Research Council, Washington, D. C., 1929. 199 pp. Price, \$2.00.

The law pursues us even after we are dead. Many important legal principles are involved in such matters—as the status of death itself, the ownership of

dead bodies, their disposition, their exhumation after burial, and post-mortem examinations. This bulletin presents a studious and comprehensive survey of existing state laws on these points and of the common law where statutes are lacking. It will be valuable to lawyers and others concerned with medico legal problems of this nature, while sanitarians will be interested in the section outlining the laws regarding the transportation of dead bodies. It is well printed and has geographical and topical indexes. The author has made a real contribution to one phase of medical and public health jurisprudence.

JAMES A. TOBEY

Statistical Reference Data—Compiled by Godias J. Drolet and Marguerite P. Potter for Committee on Neighborhood Health Development, March, 1930. 28 pp., mimeographed.

This Statistical Reference Handbook has been assembled to assist in visualizing health districts for the proposed health centers of the City of New York. Health districts for the five boroughs composing Greater New York are shown on health area maps while on similar maps the general death rate and infant mortality rate for 1929 are charted.

Graphic presentations of the registration of new cases of pulmonary tuberculosis, the number of cases of the principal communicable diseases reported, the elementary school registration and the distribution of hospitals and clinics over the various districts are additional features of this booklet which will be invaluable to persons interested in neighborhood health development and in the provision of adequate health services throughout the city.

The trend in population of the various districts, comparative rates of mortality, contagion and birth are presented in tabular form and serve to interpret further the health conditions and needs of each particular area. A. W. FRAAS

Our New Religion. An Examination of Christian Science—*By H. A. L. Fisher. New York: Jonathan Cape & Harrison Smith, 1930. 201 pp. Price, \$2.50.*

This book is described as a study of Christian Science as a social phenomenon. The author maintains that it "has succeeded negatively by failing to practice what it preaches or to regard what it dislikes," and in our opinion, sustains his thesis.

The book is divided into three parts: The Prophetess, The Creed, and The Church. Although the entire book is well documented, and it is hard to see where any exception can be taken to the statements made, the first two parts especially are historical, and apparently beyond controversy. The third part is, in our opinion, equally sound, though we presume the adherents of the cult will find some objections to it.

The whole book is written as a careful study, not in the spirit of controversy, but as an inquiry and analysis. We consider it one of the best of the many which have been written about this curious faith. M. P. RAVENEL

Yourself, Inc.: The Story of the Human Body—*By Adolph Elwyn. New York: Brentano's, 1930. 320 pp. Price, \$3.50.*

This popularized account is sufficiently simplified so that it can be read with profit by a high school freshman, or any person who lacks any knowledge whatever as to the parts and functioning of the body. Sustained interest would seem to require less effort if the author had avoided unnecessary comparisons—although a knowledge of popular taste may have decided his use of them.

The scope, style and depth of the book can be estimated by a perusal of one sentence: "Yet the living body, though a coördinated mechanism with a definite identity, is in reality a complex world of its own, a commonwealth peo-

pled by unaccountable thousands of citizens varying in size, and shape and professional activity." There are 17 chapters in the book on subjects such as the cell, the living membranes, the building trades and their strange associates, the transportation system, etc., and a short résumé of medical progress.

The 70 illustrations are excellent. The drawings and photographs, if studied by themselves, will give the reader some clear conceptions as to cell division, cell structure, various kinds of membranes, the main routes of body transportation, etc. In the first chapter of the book the author has included a few early drawings, as for example (Figure 5) muscle studies by Leonardo da Vinci, which the reader will find of interest.

ESTHER W. STEARN

Etudes sur le Cholera—*By F. d'Herelle, R. L. Malone, and M. N. Lahiri. Alexandria, Egypt: Arturo Serafini, 1929. 191 pp.*

Therapeutic work with bacteriophage has attracted considerable attention during the past ten years and has aroused no less controversy. Consequently, when it became known that d'Herelle was undertaking experiments with cholera in India his reports were awaited with eagerness and criticised with avidity when they first appeared in preliminary form. The entire investigation has been reported in the volume under review and gives in minute detail every step of the work performed. The actual therapeutic experiments themselves form but a small portion of the work and have already been criticised because of the failure of others to obtain similar results.

One cannot read this book without being impressed with the extreme care with which much of the work was done and with the completeness of the description of the experimental method. This fact in itself makes it imperative that future investigators follow the tech-

Pulmonary Tuberculosis in Students*

LEE H. FERGUSON, M. D.

Health Service, Western Reserve University, Cleveland, O.

THERE can be no doubt that pulmonary tuberculosis in students is still a serious and unsolved problem which has not received the attention it deserves. So far as I know, no paper has ever been read before this association on the subject. In the *Proceedings of the American Student Health Association* I found that the last paper given on tuberculosis was by Dr. J. A. Myers and Dr. W. B. Shepard of the University of Minnesota on January 1, 1925.¹ Their paper is a record of 4 years' experience and covers 152 cases. It is possible that the reason our attention has not been attracted to this subject before is that many of the cases of pulmonary tuberculosis develop after graduation and for this reason do not fall under the observation of the Health Service. Our problem is chiefly the detection of tuberculosis in its early stages and arrested cases.

Pulmonary tuberculosis between the ages of 16 and 25 is usually of the adult type and, while it cannot be definitely proved, usually represents a new infection. The so-called infantile type, although it starts in the lung tissue, involves chiefly the tracheobronchial glands and constitutes what we now know as hilum tuberculosis. Probably most people who reach adult life, especially those who live in cities, have had an infection of this kind of greater or less extent and the X-ray may show some evidence of it in the hilum of one or both lungs. The adult type commences in the apex of the lung and is unaccompanied by tuberculous lesions of the adjacent lymph nodes.

In addition to the healed infantile lesions which most of our students will show, many of them will have pulmonary tuberculosis of the adult type. These may be apical or, as some writers are now calling them, infra-clavicular in location, and in any stage of development. The process may be latent with no signs or symptoms and only detectable with the X-ray. Again, it may be moderately advanced with definite but meager clinical signs, with no symptoms but with confirmatory X-ray evidence of lung pathology. Also, the process may

* Read at the Sixth Annual Meeting of the Ohio Student Health Association, Columbus, O., April 4, 1930.

be far advanced with abundant clinical signs, slight or marked symptoms, and with X-ray evidence of a serious lesion.

I have had considerable difficulty in finding any accurate figures on the incidence of tuberculosis between the ages of 16 and 25. Hetherington² stated that in Philadelphia, between the ages 12 and 18, 0.6 per cent had manifest tuberculosis, 0.8 per cent latent apical tuberculosis, and 1.2 per cent latent infiltration of childhood type. This makes a total of 2.6 per cent detectable tuberculous lesions in that age period. Similarly, from the work at the Henry Phipps Institute,³ we learn that infiltrating lesions of the lungs, including both latent and manifest, are found in 2.0 per cent of boys aged 12 to 20 and in 3.4 per cent of girls.

From the evidence presented, I think we are safe in assuming that on admission to college 2 to 3 per cent of our students should show infiltrating lesions of the lungs. From the report of Dr. Myers and Dr. Shepard on conditions at the University of Minnesota and from our experience at Western Reserve University, I am led to believe that in varying degrees there is a tuberculosis problem at every institution of higher education in the country. In the school year 1927-1928 at Western Reserve we had 7 cases of tuberculosis, 5 girls and 2 boys, and 52 cases who had been in contact with tuberculosis. Two of the positive cases died during the year. In the school year of 1928-1929 we had 17 cases of tuberculosis, 12 boys and 5 girls, and 106 contact cases. There was 1 death and 2 students left college to go to sanatoriums.

Now let us enumerate without comment some of the factors in student life which may influence the development of tuberculosis. You are already familiar with these and it will not be necessary to elaborate upon them. They include change of climate, too strenuous and poorly organized social life, outside work, poor health habits, and neglect of upper respiratory infections. Under poor health habits might be enumerated lack of sleep, over-work, over-fatigue, poor food, poor living conditions, neglect of ordinary upper respiratory infections and nervous strain.

Perhaps you would be interested in a brief résumé of what I regard as a satisfactory program for the control of tuberculosis in students. The starting point is an adequate history of each individual, giving in detail the facts of his family life and his own life up to the time of his admission to college. It is very unwise to depend alone for this information on the written statement of the student which has been given on a health service blank. The examiner should in every case question the individual carefully in order that hidden and

obscure things may be brought out. Often that which in this history has been called asthma, bronchitis, pleurisy or nervous breakdown, will be found to have been tuberculosis. This history of tuberculosis in the individual or family is of great importance, for it determines how the student shall be handled while in college.

Not only is an accurate history necessary but a thorough physical examination is equally important. The initial examination should be very thorough and complete, and my own feeling is that each student should have a similar examination every year. I realize that some of you are not thoroughly convinced that this is essential but speaking from the standpoint of tuberculosis and knowing full well how insidious it may be in its onset, I feel sure that this yearly examination is an essential. In order to discover the early and latent cases of tuberculosis, the lung examination must be as complete as the one which a tuberculosis specialist would make, and should include coughing and breathing. I feel sure that without coughing many of these cases will be missed.

Austrian⁴ states:

The most constant and significant sign of tuberculosis of the lungs is a shower of medium moist inspiratory rales heard constantly over one or the other apex, in the first or second interspace, or above the spine of the scapula with or after expiratory cough. In patients with recent infiltration, these adventitious sounds are not audible during quiet breathing but are heard only during forced respiration or are elicited by a quiet cough made at or near the end of expiration. Often the reason that they are not heard is because the observer does not instruct his patient to exhale first, then to cough gently, and then inhale while he, the listener, concentrates his attention upon the sounds heard during the cough and the beginning of the succeeding inspiration.

Admitting that we have been able to obtain from the student an accurate family history, and a complete history of his own health up to the time of his admission to college, and also that he received a thorough examination on admission and yearly thereafter, what will be the next step in our program for the control of tuberculosis? These histories should give us a complete list of all students who have been in contact with tuberculosis in their families or elsewhere. Of course there are many cases of tuberculosis in families that are not known and also many where the parents have not told the child the real nature of the disease from which they have suffered. Besides there is the large group of cases where, although tuberculosis has been known to exist, the fact has been carefully concealed from the general public. As it is well known that active tuberculosis in the family is the chief source for the spread of tuberculosis, it is extremely important that

all of these contact cases be very carefully handled. This would involve an X-ray of the lungs soon after the initial examination has been made. Even if negative, the student should have repeated physical examinations at intervals of 3 to 6 months throughout his entire college course. The X-ray should be repeated once a year even though there are no signs or symptoms of pulmonary disease. The importance of this will be brought out later in discussing the arrested cases.

In addition to the above there are many other factors which enter into the proper care of these contact cases. For instance, should they at any time during the year develop upper respiratory infections, their lungs should be repeatedly examined and, in addition, if signs are found suggesting even a bronchitis, the X-ray should be repeated. We are commencing to realize that upper respiratory infections play a very important part in producing mediastinal and pulmonary diseases and it is very probable that if the lungs are examined during even a mild so-called "cold," lung signs may be elicited which would lead to a diagnosis of pulmonary tuberculosis. So impressed am I with this one phase of upper respiratory infections that we have made it practically a routine procedure in our Health Service to make a lung examination in all cases although the symptoms may be almost entirely confined to the nasal passages or pharynx.

The habit life of all the cases that have been in contact with pulmonary tuberculosis should be carefully regulated. In other words, although the disease cannot be demonstrated clinically or otherwise, they should be regarded as cases of latent tuberculosis and treated accordingly. This should not be carried to the point of arousing their suspicion or causing any needless worry in regard to their own condition, but they should be taught to treat the matter of their habit life in a sane, sensible light. It is obvious that if a student who is a contact case is working his way through college and is subjecting himself to unusual strain he may be in grave danger of developing active tuberculosis. Last year we had two such cases. The balance by which the body is able to resist an invasion of tubercle bacilli is an extremely delicate one and may be tipped in favor of the invading organism by over-fatigue, lack of sleep, long hours of study, nervous strain, lack of exercise in the open air, poor food, and many other things which enter into the habit life of the individual. Also these students should be taught to consult the Health Service for even the slightest illness, especially upper respiratory infections, chest pains, loss of weight and loss of strength.

Last year we had under observation 106 tuberculosis contact cases.

At present we are in the midst of having lung X-rays taken of all of our contact cases. From my own experience and that of the Henry Phipps Institute,⁵ I am firmly convinced that the X-ray is one of the most helpful means for the diagnosis of latent and arrested pulmonary tuberculosis. The X-ray may show extensive lung involvement where the lung signs and symptoms are either meager or entirely absent. Reid⁶ reports that in the fluoroscopic examination of 4,883 applicants for employment by the Metropolitan Life Insurance Company, 59, or 1.21 per cent, passed with negative chests on physical examination, showed anatomical tuberculosis.

With these facts in mind I feel quite certain that the time is coming when we will regard a routine lung X-ray as an essential part of every complete examination. The justification for this procedure rises in the fact that many of our students have been exposed to unknown focuses of tuberculous infection in their homes, and at the time of admission, although they may give a negative history, they may very well be either latent or arrested cases of pulmonary tuberculosis. Many of these, no doubt, would be discovered by routine X-rays and the problem is simply one of reducing the expense of such a procedure to a point where it can be consistently borne by our Health Service budgets. Certainly at the present time we are entirely justified in having X-rays of all of our contact cases and of all suspicious cases with lung pathology and symptoms such as loss of weight, loss of strength and low vitality. When we have obtained from each new student a complete history, when we have given him a complete and thorough physical examination and have obtained an X-ray of his lungs, I feel sure that on admission we will find many cases of pulmonary tuberculosis which escape us at the present time.

In addition to the contact cases the inventory of our student body is sure to reveal a considerable number of arrested cases of pulmonary tuberculosis. Many of these will not know that they have had tuberculosis and recovered from it. This group, like the contact cases, demands very close attention from the Health Service. The reason for this is that almost without warning an arrested case may become active and it is surprising how quickly this change may occur. I could give you a case report where within 10 days the signs changed from a quiescent condition to marked activity. No doubt many cases which are regarded simply as hard colds or coughs which hang on, are in reality tuberculosis. As in regard to the contact cases, the arrested cases should be carefully educated to come to the Health Service for all sorts of minor ailments. Likewise their habit life should be extremely carefully adjusted and if necessary their academic schedule

should be reduced to the point where they can carry the load without danger to their health. It is particularly important also that they should treat with the utmost respect all infections of the upper respiratory tract.

The important consideration in these arrested cases, which have been picked up either through physical signs or X-ray, and also in the contact cases, should be frequent physical examinations and frequent X-rays. In general an arrested case should be examined at least every 2 months and have an X-ray every 6 months. The reason for this is that we are not at all sure that lack of physical signs is proof that the process in the lungs is not spreading. The student may seem perfectly well, may have no symptoms, no loss of weight, and no extension of clinical signs, and still the X-ray may show a definite extension of the process in the lungs. It is this which makes me recommend the repeated and frequent use of the X-ray in these cases. We have come to regard a definite X-ray spread as just as serious a matter as a clinical and symptomatic spread, and I could show you the picture of a case which showed an extensive X-ray spread and is still clinically perfectly well. Of course, as soon as any case changes from the arrested stage to the active the indications are for the student to leave school at once and receive appropriate treatment.

Next let us consider the cases of active tuberculosis which either are found by the first examination or develop later. It seems probable that even with the program which I am proposing to you, we will still continue to find such cases. Of course all such persons should be dismissed at once in order to protect themselves and the student body. I have no doubt that one active case in a fraternity, a boarding house, or even a classroom may be responsible for the development of other cases. We have a record of an open case of pulmonary tuberculosis in a fraternity which seems to have been responsible for the development of two other cases.

Of course some of these cases which apparently develop spontaneously, as I have suggested, may represent a massive infection from contact with an open case. It seems likely that many of them are simply arrested cases of pulmonary tuberculosis which have not been discovered by the physical examination. Many of these could be picked up by the routine X-raying of each student upon admission but even then it is possible that some might be missed, for the interpretation of lung X-rays, from the standpoint of the diagnosis of tuberculosis, is still extremely difficult. Admitting that some of this group are undetected arrested cases, the importance of the yearly physical examination can be readily seen. Sooner or later they may

develop signs, and it seems probable that these may precede the symptoms. As already stated, a person may have progressive pulmonary tuberculosis and still have no symptoms whatever.

Again, some of this group may be picked up through chest examinations while they have acute upper respiratory infections. It is obvious that the acute infection may light up the arrested process in the lungs and give signs which can be detected on routine examination. It would seem, therefore, that our chief means of detecting these cases are the yearly physical examination, the lung examination during acute respiratory infections and X-rays of all cases who show symptoms suggestive of pulmonary disease. It would seem that we should constantly be suspicious of deep seated, unknown tuberculosis in all of our college students, and not neglect any means at our disposal for its detection.

Lastly in my program for the control of pulmonary tuberculosis in our students I would like to propose a few things which all of you recognize as a real menace to health in general. I mean, particularly, regulation of the social life of the students; more careful adjustment of their habit life, eating, sleep, etc.; the careful supervision of all who are doing part-time work outside of their regular schedule; the readjustment of our programs of physical education so that the program will carry through all 4 years of undergraduate work and through professional school courses. No doubt many other things will come to you which we might do in order to protect the general health and thus prevent much tuberculosis.

Two thousand years ago a great teacher said: "Ye shall know the truth and the truth shall set you free." Nowhere is this truer than in the realm of health. We should, by patient and coördinated effort, be able to strike the shackles of an insidious disease from the lives of hundreds of those entrusted to our care. Then and only then can we count our task as well done. Who can measure the new power, the new strength, the added capacity for happiness, growth and service that may be released thereby?

SUMMARY

1. Pulmonary tuberculosis in students is still a serious and unsolved problem. It is usually of the adult type, insidious in onset and difficult to detect except by X-ray when there are no symptoms.
2. The incidence of pulmonary tuberculosis in students is hard to determine; it probably is between 2 and 3 per cent.
3. Special factors in student life which may favor the development of tuberculosis are: change of climate, too strenuous and poorly organized social life, outside work, poor health habits and neglect of upper respiratory infections.

4. A program in detail is presented for the solution of the problem:

Adequate history

Physical examination of all students on admission and yearly thereafter

Lung examinations to be especially thorough

X-ray of lungs of all students on admission is suggested

Special care and examinations (including X-ray) for—

a. Contact cases

b. Arrested cases

c. Cases with suspicious symptoms

d. Upper respiratory infections

Early detection of active cases and immediate dismissal to avoid spread of infection in dormitories, etc.

More careful adjustment of the entire habit life of students including social activities, outside work, recreation, etc. The recommendation is made that physical education programs should continue throughout each year of the entire undergraduate and professional school courses.

Polish Health Centers

HEALTH centers were first developed in Poland in 1925 through grants from the Rockefeller Foundation. On January 1, 1929, there were 140 health centers in Poland.

Each center is required to attend at least to the health of mothers and infants and anti-tuberculosis efforts; several centers have also organized anti-venereal, anti-trachoma and dentistry sections; some are engaged in the anti-alcohol campaign and in combating malaria; school hygiene is almost always among their activities.

The cost of building, management and upkeep of the health centers is met by the big urban communes, the communal administration of the several districts and partly by the sickness insurance funds; the state also makes certain grants to encourage them.

Prof. W. Chodzko, writing on "Making the Country Healthy" in the *Bulletin de l'Office Internationale d'Hygiene*, 1928, thus expresses himself:

If these Health Centers go on developing as rapidly as they are doing at present, we can expect our country soon to be covered by a network of institutions, embracing all the problems of public health and preventive medicine, and the health organizations of Poland, once this plan has been put into effect, will be definitely established on a solid, practical, and rational basis.—

Physical Measurements of One Thousand Smith College Students

FAITH FAIRFIELD GORDON, M. D.

*Psychiatrist, North Carolina College for Women, Greensboro, N. C.**

IN a study of physical measurements of young women of today and of 40 or 50 years ago, it is difficult to find groups sufficiently comparable. The girl of today is an athletic person accustomed from early childhood to active participation in strenuous outdoor games. She has never known the restraint of heavy, tight clothing, and the equally curbing influence of public censure demanding that she be sedate. The increase in her physical activities throughout childhood and adolescence should show itself in the development of the grown woman.

The woman's college offers an excellent opportunity for a study of physical measurements of a large group of individuals finely selected in regard to age, intelligence and health; yet standards of physical measurements of college women are not readily available. The personnel of the hygiene department has generally too full a schedule of examinations, college dispensary and infirmary work, to attempt to correlate or interpret the findings which it records. Whether the group of college women of today and of 40 or 50 years ago is similar may also be questioned. It is now the fashion to go to college, and the girl expects to train herself to be self-supporting. In the past it was the unusual girl who went to college. She had special abilities, or keen ambitions, or for some reason wanted to gain recognition by special attainments.

The following study of physical measurements of 1,000 Smith College students was made possible through the courtesy of the college physician, Dr. Anna Richardson, and other members of the hygiene department, in allowing the use of records jointly compiled. In selecting the material the following restrictions have been made: All cases spent a limit of 4 years at college and graduated between the years 1926 and 1928, inclusive. The age range on entering college was restricted to those entering between 16 and 20 inclusive.

* Formerly Assistant Physician, Smith College, Northampton, Mass.

In measurements of height the horizontal sliding square was used, the vertical bar being marked in inches. In measurements of height two records may be made—the first the student's height with her usual posture, and the second with her best or corrected posture. For this study the first measurement has been used. The records are taken from the student's examination on entering college in the fall and again just before graduation in June, 4 years later.

The age of the entering student is given at the nearest birthday. Since the measurements are not exactly 4 years apart it is apparent that if the age at nearest birthday of an entering student is 17, her age at nearest birthday on graduation may be 20 or 21. No correction has been made for this since it may be assumed that there can be but slight differences in the measurements in the few months.

In comparing weights of students to standard scales it is often found that the apparently healthy girl may vary from 10 to 15 pounds below the standard, or 15 to 20 pounds above. This is not always due to malnutrition or obesity but may be explained on the basis of physical builds. These have been described as slender, intermediate or stocky. Dr. Goldthwait has described the two extremes as follows:

The slender flexible individual has long been selected for the contortionist, the fancy dancer, the pole vaulter, the short distance runner. He has been the pioneer of the race, the "Uncle Sam" type. . . . The heavy or stocky individual with thick chest, heavy limbs, broad hands and feet has been used as the weight lifter, the hammer thrower, the shot putter, the wrestler, the football center, the slower moving conservative or stabilizer of the race, the "John Bull" type.¹

Standards by which to measure accurately variations in build are not available and probably would be impractical in a physical hygiene department. In this study the students are included in the intermediate group unless they are definitely of the slender or stocky type.

Since the study was restricted to students entering college between the ages of 16 and 20 and only those students were included who completed the course and graduated 4 years later, the measurements included data from examinations of women between the ages of 16 and 24 inclusive. Of these students 7.3 per cent entered college at 16, 31.5 per cent at 17, 42.6 per cent at 18, 16.4 per cent at 19 and 2.2 per cent at 20.

On grouping the students according to type of build it is found that a higher percentage of students of the stocky type starts college at an earlier age, the proportion decreasing from 28.8 per cent at 16, to 17.7 per cent at 17, 16.6 per cent at 18, 12.8 per cent at 19 and 14 per cent at 20. The group of students entering at 16 contains only 19.1 per cent of the slender type, but this percentage rapidly rises to

TABLE I

MEDIAN WEIGHT OF ENTIRE GROUP OF STUDENTS AT ENTRANCE AND GRADUATION

Entrance		Graduation	
Age	Weight	Age	Weight
16	130	20	129
17	126	21	126
18	121	22	122
19	126	23	123
20	124	24	128

30.2 per cent at 17, 32.2 per cent at 18, 43.9 per cent at 19 and 45.4 per cent at 20. The percentage of students of the intermediate type remains fairly constant for all ages, varying from 40.9 to 52.1 per cent. In the entire group of students, regardless of age, there are 50 per cent of the intermediate type of build, 32.8 per cent of the slender build, and 17.2 per cent of the stocky build.

The fact that the sturdily built girl is sent to college earlier may be due to several factors. The first is that of disease experience. The person with a slender build is considered by hygienists a greater health problem throughout childhood.¹ Another factor may be a difference in parental attitudes. The slender girl may seem merely a child to her parents whereas the stockily built girl is expected to be self reliant. Finally, a study of menstrual periods indicates that the girl with the slender build is physically immature. This is consistent with Baldwin's findings that the tall heavily built girl tends to mature earlier.² It may be that this immaturity is not only physical, but that the girl is actually less prepared to be away from home.

Catamenia began during the 13th year in 37 per cent of the total group, and in 81 per cent had been established at either 12, 13 or 14. The variations in age at onset range from 9 (1 case) to 19 (1 case). Considering age of onset of catamenia in relation to type of build, catamenia began by the end of the 14th year in 94 per cent of the stocky type, 91 per cent of the intermediate type, and only 85 per cent of the slender type. The age of onset varied in the slender type from 10 to 17 inclusive, the median age being 13 years and 10 months. The onset range for the stocky type ran from 11 to 16 inclusive, and

TABLE II

MEDIAN WEIGHT OF STUDENTS GROUPED ACCORDING TO AGE AND TYPE OF BUILD

Type	Median Weight								
Slender	112	111	111	111	114	114	116	115	113
Intermediate	125	125	123	124	124	126	126	123	120
Stocky	145	148	144	147	143	147	135	144	144
Total	130	126	121	126	127	126	122	123	128
Age	16	17	18	19	20 ¹	21	22	23	24

1. Students entering college at 20.

the median age was 13 years and 3 months. In the intermediate type the median age of onset was the same as the median for the entire group, 13 years and 6 months.

The periodicity of menstruation was of the 28-day type in 67 per cent of the entire group; 2.5 per cent had a periodicity of 21 days; 4 per cent each of 30 and 31 days; 7 per cent varied between 21 and 28 days; 5 per cent had a periodicity of 35 days, and 9.4 per cent had irregular periods varying between 5 and 8 weeks. Finally, 1.2 per cent had irregular very infrequent periods, 7 of this group of 12 belonging to the slender type and the remaining 5 to the intermediate. In relation to type of build, only 10 per cent of the stocky type did not have periods once a month or more frequently, whereas 19 per cent of the slender type had periods every 5 weeks or less often.

The median weight of the entire group of 16-year old students entering college was 130 pounds, of 17-year old students 126 pounds, of 18-year 122, of 19-year 126, and of 20-year 124 pounds. The chief factor determining these weights was the proportion of slender and stocky students in the group, there being a larger proportion of stocky type students in the 16-year group. There was no consistent increase in weight in the students during college. The median weights of students entering at 16 and graduating at 20 were 130 and 129 pounds. The median weights at entrance and graduation of 18-year old students were 121 and 122 pounds, of 19-year old students, 126 and 123 pounds, and of 20-year, 124 and 128 pounds. The median weight of 17-year old students was the same, 126 pounds, on entrance and graduation. Tables I and II show the median weights of students grouped according to age and height in inches, and the median weight of each type grouped according to age.

The median weight of the slender type, grouped according to age, ranged between 111 and 116 pounds. The greatest weight in students of this type was 142 pounds, and the least weight 90 pounds. The median weight of the stocky type ranged between 135 and 148 pounds, the greatest weight being 206 pounds, one case, and the least 119 pounds. The weight of the intermediate group ranged between 120 and 126 pounds, the greatest weight was 151 pounds and the least 103 pounds. Although the examiner may have considered some of these students over or undernourished for their height and build, no note has been made of these observations.

There was no consistent increase in height in the group as a whole or in the group divided according to type. The median height determined for each age level and type of build ranged between 63.5 and 65.4 inches. Table III shows median height in inches of students

grouped according to type of build and age. The height level varied from 58 to 70.9 inches.

2. Students graduating at 20.

To obtain comparative studies of physical measurements of school and college students, records from twenty-five to fifty years ago, Baldwin's bibliography has been used.² In each case the group compared has consisted of school or college students. The groups studied are listed as follows:

1. A report of 10,904 female school children in Boston, studied by Bowditch in 1875³

2. Measurements of 1,600 Oberlin students made by Hanna in 1893⁴

3. Porter's study of 16,527 female school children in St. Louis in 1894⁵

4. Gilbert's study of 50 women students at the University of Iowa in 1897⁶

5. Hastings' study of 7,069 University of Nebraska women students in 1902⁷

6. Baldwin's study of 88 Swarthmore students published in 1921⁸

With the exception of Gilbert's group and the upper age levels of Hanna's group the median height of the Smith College students at each age level is greater than those found in the comparative studies. The median weight of Smith College students of the intermediate and stocky type is greater than the weight listed in the comparative studies, with the exception of Gilbert's records. There has been no consistent increase in weight with age in the Smith College group as recorded in each of the comparative studies. Tables IV and V show the

Tuberculous Patients in New Jersey Sanatoriums

EMIL FRANKEL AND HELEN E. HEYER

*Director and Research Assistant, Research Division, New Jersey State Department
Institutions and Agencies, Trenton, N. J.*

THIS study covers all the admissions to the state and county sanatoriums during the year ending June 30, 1929, and all the discharges from and deaths in them for the same period. It was undertaken for the purpose of throwing light upon the developments in the tuberculosis sanatorium field in New Jersey; the characteristics of patients entering them; the conditions under which patients leave tuberculosis institutions; the social and economic problems created in the home by the hospitalization of the individual patient; and the extent to which communities meet their tuberculosis problems and carry out the work of tuberculosis prevention effectively.

As a background Table I is presented showing the extent to which New Jersey has provided sanatorium facilities during the last decade.

A 52 per cent increase in the number of patients in state and county tuberculosis sanatoriums per 100,000 population has occurred during the 10-year period 1919–1929. This means that, out of every 100,000 population, 48 tuberculous patients were hospitalized in 1929 as against 32 in 1919. The actual number in the institutions has risen from 996 in 1919 to 1,887 in 1929, an 85 per cent increase.

These figures do not mean that there is an actual increase in the

TABLE I
Population All N. J. Sanatoriums as of June 30
All Sanatoriums

Year	Number	Rate per 100,000 Population of State	State Sanatorium	County Sanatoriums
1929	1,887	48.4	356	1,531
1928	1,675	43.8	289	1,386
1927	1,599	42.6	286	1,313

1921	1,124	34.2	235	889
1920	998	31.3	225	773
1919	996	31.8	225	771

number of tuberculous in the state, as only 5,204 new cases were reported in 1929 as against 7,460 in 1919, and the death rate for the period shows a decrease of 30.0 per cent; they indicate rather that New Jersey is taking better care of its patients and making available greater sanatorium facilities where they may be treated, and removed from the community where they are a source of infection. Clinics are seeking out active and contact cases for hospitalization and the people are recognizing the value of sanatorium treatment in an increasing measure.

FIRST ADMISSIONS

During the year ending June 30, 1929, 3,075 persons entered sanatoriums (1 state and 11 county); of these, 83.1 per cent were first admissions and 16.9 per cent readmissions. Of the total of 3,075 admissions 54.3 per cent were males and 45.7 per cent females. Eleven patients were admitted by transfer from one sanatorium to another in the state. Discharges numbered 2,136 and deaths 727. On June 30, 1929, there were 1,887 patients in these institutions of whom 55.9 per cent were males and 44.1 per cent females.

Particular emphasis is placed upon an analysis of the characteristics of first admissions—persons who have never before been in any institution for tuberculous diseases. First admissions are considered the best indexes of the incidence of the disease because they more nearly indicate the onset, and at what age, in which sex, in which na-

Not stated	1	1	—	0.1	0.1	0.0

Of the total of 2,200 first admissions suffering from pulmonary tuberculosis only 18.7 per cent were received in the minimal stage, 40.7 per cent were in the moderately advanced, and 40.6 per cent in the far advanced stages. The goal should be to treat all cases in the minimal stage when recovery is particularly certain, so that the moderately and far advanced stages will not be reached and will not as now be sources of infection in the community. Therefore any county showing a large proportion of minimal and a small proportion of far advanced cases entering sanatoriums usually has good clinical service, a good follow-up of contact cases, and a good educational program that has been carried on over a period of years.

AGES OF FIRST ADMISSIONS

Forty-two per cent of first admissions were between 15 and 29 years old; 12 per cent between 15 and 19; 15.5 per cent between 20 and 24; and 14.6 per cent between 25 and 29.

Table III shows considerable age differences between the males and the females; 22 per cent of the males as against 30 per cent of the females entering sanatoriums being less than 20 years old. In the age group 20-34 about 24 per cent were males while more than

37 per cent were females. Only after 34 years is there a proportionally larger number of admissions among males than females.

The fact that 42 per cent of the patients entering New Jersey sanatoriums were between the ages of 15 and 29 calls for decided action on the part of all tuberculosis and health agencies. For those young people to be hospitalized when they are finishing their education and beginning business or professional careers means a great economic waste to the community and state as well as a serious handicap in their personal development. The fact that 15 per cent of females entered between the ages of 15 and 19 indicates the great need for health education among girls of high school age. That the high admission rate among females rises far above the males in the 15 to 29 age group and then falls off rapidly calls for action along different lines. The male admission rate remaining consistently high from 20 to 44 years of age emphasizes the relation between industry and tuberculosis and suggests that the example of organizations which are providing health examinations and education among their employees should be followed extensively.

COLOR OF FIRST ADMISSIONS

In New Jersey the case rate for tuberculosis is approximately four times greater among the colored than among the white; the death rate is likewise four times greater. Although the death rate for whites is decreasing rapidly, that for colored is on the upward grade. Eleven per cent of first admissions to the state and county sanatoriums are negroes although they constitute only about 4 per cent of the population. Arresting is the fact that one-tenth of all the living cases of tuberculosis on record by the State Board of Health are of negroes. That 20 per cent of the deaths from tuberculosis are among negroes reveals a still more serious condition. It is evident that many more cases proportionately occur among the negroes and that a much larger proportion prove fatal, perhaps because they contract a more virulent form of the disease or because they, who especially need hospitalization, are not finding adequate facilities for the attention they should have. For the sake of community health, therefore, the problem of tuberculosis and the negro must be met as effectively as possible and the negro must be given all the safeguards that science can command.

MARITAL CONDITION OF FIRST ADMISSIONS

Of 2,117 first admissions over 16 years of age 38.4 per cent were single, 53.8 per cent married and 7.7 per cent widowed or divorced. Such a large proportion of married patients is an indication of the

seriousness of the economic problem involved. During the hospitalization of these cases, most of which are in the moderately advanced or far advanced stages when longer periods of care are necessary, the family is either without a wage earner or without someone to maintain the home. The family economic and social obligations are responsible too for the fact that a large number of the patients remain too short a time in the sanatorium to receive adequate treatment.

Some of the sanatoriums with active social outlooks and some tuberculosis associations endeavor to procure financial assistance for the families of patients in order that the latter may have the freedom from worry and peace of mind that will permit their taking time for recovery. The complete relaxation necessary for cure is impossible when the patient is "harassed by worries of home, depressed by prospects for the future, fidgety for want of something to occupy the mind and hands, restless from long waiting, and impatient to have done with the tedium of institutional régime."

READMISSIONS

Twenty persons entered tuberculosis institutions for the second, third or fourth time for every 100 entering for the first time. Readmissions are those who have previously been under treatment in some hospital for tuberculous diseases, except those few transferred directly from another institution for tuberculous diseases in New Jersey.

Of 467 readmissions with pulmonary tuberculosis, more than half were far advanced as compared to the 40 per cent for first admissions, and 9 per cent had minimal tuberculosis as contrasted with 19 per cent of the first admissions. This indicates need for a more careful analysis of the readmitted cases, covering their condition on discharge after the first admission, the reason for leaving the sanatorium (especially against the physician's advice), the length of time between discharge and readmission, the extent to which clinical follow-up service was used and the physical, industrial and social life of the patient during the interval.

CONDITION ON DISCHARGE

Twenty-seven per cent of the 2,136 patients discharged from state and county sanatoriums during the year ending June 30, 1929, were quiescent, apparently arrested or arrested; 48 per cent were improved; 23 per cent unimproved; and 2 per cent non-tuberculous and under observation.

There is no better argument for the early diagnosis and treatment of pulmonary tuberculosis than the figures in Table IV, which show

TABLE IV

Condition on Admission to All Sanatoriums	Total Discharged	Percentage Discharged as					Non-tuberculous	Observation
		Arrested	App. Arrested	Quiescent	Improved	Unimproved		
All Conditions	2,136	4.3	11.3	11.6	48.4	22.5	1.7	0.2

Not Diagnosed	4	—	—	—	—	100.0	—	—
Observation	2	—	—	—	—	—	—	100.0

as arrested, apparently arrested, or quiescent 51 per cent of those discharged who entered with minimal tuberculosis as contrasted with 31 per cent with moderately advanced tuberculosis, and only 16 per cent with far advanced tuberculosis. Again contrast the 8 per cent of the cases minimal on admission discharged as unimproved with 46 per cent of the far advanced cases discharged as unimproved.

LENGTH OF STAY OF PATIENTS DISCHARGED DURING THE YEAR

It is significant to note that of the 2,136 patients leaving sanatoriums almost 40 per cent stayed less than 3 months. Of those who entered with pulmonary tuberculosis 39 per cent remained less than 3 months, 16 per cent less than 1 month, 12 per cent between 1 and 2 months, and 11 per cent between 2 and 3 months.

Patients staying less than 3 months include 46 per cent of the discharges entering with far advanced disease, 34 per cent with moderately advanced, and 39 per cent with the minimal, which latter

TABLE V

Patients Discharged Alive from All Sanatoriums

Condition on Admission	Number	Percentage Discharged After Treatment of						
		Less Than 1 Mo.	1 Mo. and Less Than 2	2 Mos. and Less Than 3	3 Mos. and Less Than 6	6 Mos. and Less Than 1 Yr.	1 Year and Less Than 2	2 Yrs. and Over
All Conditions	2,136	15.7	12.3	10.9	23.0	24.6	10.5	3.0
Pulmonary								
Minimal	433	10.8	14.3	13.9	26.5	24.1	8.0	2.4
Mod. Advanced	848	13.9	10.3	9.7	23.4	27.9	12.6	2.2

Not Diagnosed and Observation	6	83.3	—	—	—	—	16.7	—

group would be expected to be much larger than the other two (Table V).

That the condition of the patient on discharge is closely related to his time in the sanatorium is shown in Table VI. Those with a better condition on discharge are those with a longer period of hospitalization. Thirteen per cent of those discharged as arrested, apparently arrested, or quiescent stayed less than 3 months as contrasted with 65 per cent discharged as unimproved staying less than 3 months. Twenty-one per cent of those discharged as unimproved were actually under sanatorium care less than 1 week. The 26 per cent far advanced cases who were in a sanatorium over 3 months and less than 1 year were probably so far advanced on admission that they needed long periods of hospital care or had delayed treatment so long that improvement was difficult or impossible.

TABLE VI

RELATION OF LENGTH OF STAY TO RECOVERY

Tuberculous patients even in the earliest stages of disease cannot expect to be cured in a few weeks. One of the major problems in the treatment of tuberculosis is to induce the patient to continue sanatorium treatment for a sufficiently long time. There is need for more educational work against impatience in recovery time and for the importance of early and continued treatment. It is not fair to the institutions to ask them to begin treatments which they are not given an opportunity to finish; neither is it fair for an uncoöperative patient to occupy a bed which would prove a real cure to a patient who is prepared to meet the instructions of the physicians in every way. Doctors, public health nurses, clinics and tuberculosis leagues should impress upon the patients before they enter the sanatorium the necessity of planning to remain until discharged by the superintendent in order that they may be restored to health that will have every chance of being permanent.

A social service worker of the sanatorium is a valuable asset in this field since, as the connecting link between the patient in the institution and the family at home, she may secure the coöperation of the patient's family in inducing him to remain, may quiet his restlessness by reports of the economic and social condition of his family, make arrangements for the financial care of the family during the absence of the bread winner, and be helpful in arranging proper home conditions to prevent tuberculosis in other members of the family, and to further the cure of the patient when discharged.

DEATH RATE IN SANATORIUMS

In the state and county sanatoriums 727 deaths occurred during the year ending June 30, 1929—a death rate of 15.3 per 100 under treatment. In Glen Gardner, the State Sanatorium, which takes only milder cases among whom are a number of children, has a death rate of 1.9 per 100 while in the county institutions the death rates range from 8.1 per 100 to 36.6.

The death rates of the institutions are modified by the proportion of far advanced cases admitted, the turnover of patients (that is, whether the population consists of many patients who stay short periods or fewer patients who stay for longer periods), and the policy of the institutions in sending to their homes those whose days are numbered and who beg to spend their last hours in familiar surroundings.

Eighty per cent of the 727 deaths in state and county institutions during the year occurred among patients entering with far advanced tuberculosis, 18 per cent among those entering in the moderately advanced stage, and less than 1 per cent among those entering in the minimal stage. These figures are conclusive evidence of the value of early diagnosis and treatment to prevent fatality.

Table VII shows that hospitalization of tuberculous patients is frequently sought too late, that even far advanced cases stay at home until the last minute.

TABLE VII

Condition on Admission	Total Deaths	Length of Sanatorium Stay Before Death								
		Less Than 7 Days	7-13 Days	14-29 Days	1 Mo. and Less Than 2	2 Mos. and Less Than 3	3 Mos. and Less Than 6	6 Mos. and Less Than 1 Yr.	1 Year and Less Than 2	2 Yrs. and Over
All Conditions	711	61	45	86	123	62	134	101	59	40
Pulmonary										
Minimal	6	—	—	1	2	2	—	—	1	—
Mod. Advanced	120	3	1	5	14	11	23	27	27	9
Far Advanced	577	57	43	78	106	49	109	74	31	30
Non-Pulmonary	5	1	—	—	1	—	2	—	—	1
Non-Tuberculous	3	—	1	2	—	—	—	—	—	—

Ten per cent of the deaths in far advanced cases occurred before the patients had been in the sanatorium 1 week, 31 per cent (178 deaths) before 1 month, and 49 per cent (284) before 2 months. Deaths due to far advanced tuberculosis on admission occurred in 442 cases of the 577 before 6 months had passed. Of the 120 deaths in cases admitted to county sanatoriums as moderately advanced, 7.5 per cent occurred in the first month, 11.7 per cent in the second month and 9.2 per cent in the third month.

CONCLUSIONS

The joint efforts of many institutions and organizations in New Jersey have contributed toward a most encouraging decline in the tuberculosis death rate—a 58 per cent drop—from 179.5 per 100,000 in 1904 to 74.9 in 1929. State and county sanatoriums, state and county tuberculosis leagues, general hospitals, clinics, schools, medical and nursing services, the State Board of Health and the State Department of Institutions and Agencies working together in a common cause have contributed to the declining tuberculosis death rate. The cumulative results show that the campaign of the public health movement against tuberculosis has been effectively organized and carried out.

From the standpoint of the tuberculosis sanatorium the problems still to be solved arise from the fact that far too many patients are entering when the disease has reached a stage at which the possibilities for recovery are less certain; that the negroes are not being adequately hospitalized although they need care more than the white race; that patients are not remaining in the sanatorium a sufficient length of time to effect a cure.

As Commissioner William J. Ellis has so well said:

“Sanatoriums must seek means of keeping the patients until they can return to the community upon the physician’s advice in such a condition that they will not be a source of contagion, and social workers of the sanatoriums or the tuberculosis leagues must seek to alleviate the economic and social reasons that make the patients return to their homes too soon.

“The problem of tuberculosis will remain active until the laity have learned to seek medical advice upon recognition of the symptoms and the physicians have been awakened to the importance of detecting and diagnosing tuberculosis in its earliest stages when these early cases may be hospitalized to insure their complete recovery and to safeguard the health of the community against infection from active advanced cases.”

NOTE: Appreciation is expressed to the sanatorium superintendents and their staffs for their faithfulness in furnishing the figures upon which this study is based, to the tuberculosis workers in the communities, to the New Jersey Tuberculosis League, and the National Tuberculosis Association, for their valuable advice in the compilation and analysis of the figures used.

MEXICAN LEADERSHIP IN PUBLIC HEALTH

NOT many months have elapsed since the Seventh Latin American Medical Congress met in Mexico City. It is, therefore, fitting that, before the end of the year, the American Public Health Association should round out its sessions at Fort Worth by a post-convention tour to this historic capital of the Aztecs, thus bringing new proof of the important rôle filled by the Republic south of the Rio Grande as a connecting link between the two great civilizations sharing the Western Continent.

The interest in Mexico in the success of the American Public Health Association is not a recent development. After the United States and Canada, Mexico was the first country to accept, as far back as 1889, the invitation to join in the work of the Association. Incidentally, this very acceptance served to emphasize the truly American character of the organization. The importance of Mexico's position in the Association from the beginning is shown by the fact that as early as 1892 the American Public Health Association had already met in Mexico City and one of her most illustrious sons, the lamented Licéaga, presided, in 1896, over the destinies of the Association whose meetings he attended as the representative of his country from 1893 to 1913.

Those fond of dwelling on the past may find much to hold their attention in Mexico. The Mayan relics have just begun to disclose the achievements of that wonderful race and its progress, even in medical subjects. Many drugs in present use have come to us from the

old inhabitants of the Anahuac plateau. Cortez had barely taken off his spurs after the *Conquista*, when he was already laying the cornerstone of a hospital, the third to be built in the Americas. This was probably about 1523, and some hundred and forty years before the first such institution for the sick was built in the English Colonies. While Mexico was not the first American country to organize a medical school, such priority belonging to Santo Domingo or Peru, medical teaching began there before 1550, and the first medical book printed in the New World (1570) was certainly that of Bravo on the dreaded "tabardillo," or typhus fever. It may be well to recall here that, in Mexico City, Anderson and Goldberger, more than three centuries afterwards, carried out their important investigations concerning the nature of this disease.

Practical sanitarians will, however, be more interested in the latest Mexican contributions to public health work. Her pioneer sanitarian, Licéaga, already, in 1893, had published the basis for a more or less uniform Pan-American sanitary policy, and Mexico was probably the first country in the world (1894) to incorporate in her maritime quarantine regulations the resolutions adopted at the international sanitary conventions. Mexico was also the cradle of the Pan-American Sanitary Bureau, and to the wisdom of her statesmen and her physicians the Pan-American Sanitary Conventions owe much of their permanence and success.

With such a history, it was, therefore, to be expected that as soon as the troublous days of the Revolution were followed by quieter times, her statesmen and sanitarians should take up anew the deferred health tasks which Licéaga was obliged to leave uncompleted.

Few countries can boast of a more comprehensive program of work than that outlined in the reports of the last two energetic heads of the Mexican National Department of Health, and in the present Director, Dr. Rafael Silva, President Ortiz Rubio has given Mexico, as the head

Rafael Silva, M.D.

of her Department of Health, a physician of international reputation, full of honors in his own country, and a man of radiant personality.

Before 1917, public health work in Mexico was entirely in the hands of local authorities, with the exception of the Federal District and the Quarantine Service, and there was lack of coördination. In 1917, the old Public Health Council, with mostly advisory functions, was transformed into a Department of Public Health, and its powers were greatly strengthened and broadened.

From 1920 to 1924 the ground was prepared for further developments by means of a campaign of public health education. This appeal to the people to coöperate in sanitary improvement was an entirely new feature in Mexico. As part of that campaign, the training of public health nurses and the establishment of a training school for physicians and nurses in public health work became an accomplished fact. At about the same time, with the aid of the Rockefeller Foundation, the campaign against yellow fever was carried to a successful termination. When President Calles took the reins of power, federal public health delegates were stationed in every state in the Republic; a compulsory vaccination law was issued and enforced; a hookworm campaign was begun on a large scale; venereal dispensaries were created; and a number of much needed public health regulations were promulgated. The old bacteriological laboratory was enlarged and developed into the present and up-to-date Institute of Hygiene.

The activities of the department embraced successively the various phases of health protection—infant mortality, communicable disease control, industrial hygiene, medical inspection of schools, railroad sanitation, and problems connected with alcoholism and the sanitation of milk and other foods. A series of censuses have been taken to determine the prevalence of such diseases as leprosy, cancer and pinto. An extensive program has been developed for the struggle against two of the worst scourges of the country: tuberculosis and malaria. Of unusual interest is the work of the new coöperative sanitary units at Veracruz and Puerto Mexico.

The hearty support rendered by the National Government to the Department of Public Health is well illustrated in the splendid new building housing the department in Mexico City, and in the funds made available for sanitary work. Under the leadership of a series of progressive men, Mexico is again assuming the rank belonging to her in the field of public health.

In conclusion, it may not be amiss to mention the fact that there are already many Pan-American congresses, Pan-American societies of medicine, of child welfare, societies for combating tuberculosis,

and others of similar import. The approaching visit to Mexico may well be used to call attention to the truly international nature of the American Public Health Association, the only organization of its kind in the Western Hemisphere.

THE SHIP DOCTOR AND PUBLIC HEALTH

THE statement that the ship's doctor has been a term of opprobrium for decades is frequently heard. Such a pessimistic attitude is not in accord with the opinion of those who travel much and have received generous, sympathetic and good care on many ships.

It may be quite apparent that some physicians on ships have been selected for most obscure reasons; that their qualifications both personal and professional are not of the standard one would insist on ashore; that their training or actions have not been the subject of inquiry from fellow physicians, such as the chief surgeon of the passenger line, but from the captains or other officers of their ships; and finally that the dignity and responsibility of their position has been wilfully ignored by shipping companies in low salaries and lax discipline. In other words, many companies follow the law to the letter in that a physician must be present on passenger ships, no matter who or how obtained.

There is, however, another side to the question—Many ship surgeons render excellent service; they are underpaid and many times not paid for services of a definitely high character; they are the health officers of the ships, and as such, of their country, and therefore have usually no continuity of service; they are the buffers to their companies in lawsuits due to accidents and other things; their living quarters and hospital facilities are generally unsatisfactory; and they have no assistants, but work long hard hours under circumstances that would make the present-day hospital interne quiver with indignation. In other words, the honest and qualified ship surgeon is a self-sacrificing and generous man, representing in one person the specialist in medicine, surgery, obstetrics, public health—and indeed embalming—at a specified compensation comparable to most menial types of work. Moreover, the ship's doctor should be the family doctor of the highest traditions and an important part of the public health service.

The pessimism of many may be eventually changed. In fact, one American company has taken steps to place its medical service on the highest type of basis. It has appointed a chief surgeon and selected the members of the staff of one of the universities as advisers in public health and tropical medicine. This momentous advance in medicine and public health service afloat will be watched with interest, and its

intrinsic value to the shipping company, if in only prestige, very great. The recent meningitis outbreak in Filipinos on ships from the Orient fully demonstrated the need for such advisory preventive and educational health measures.

MOUTH SPRAY AND PUERPERAL FEVER

PUERPERAL fever is still one of the black spots on our preventive program. In spite of the introduction of antiseptics of all sorts, the rate is still high. In England it is said not to have fallen during the past twenty years. "Despite the improvements in surgical technique and the advance of antisepsis, the maternal mortality rate has but little altered during the last decade, and sepsis is still responsible for approximately half the deaths in childbirth." America makes a bad showing in the list of nations on this score.

Obstetricians are necessarily deeply concerned, and many are avoiding the usual examinations during labor in the hope of bettering conditions. The infection occurs more frequently in hospitals than in private practice, in spite of the conveniences and care which institutional treatment provides.

A number of organisms have been incriminated—sometimes alone and sometimes in combination—but the hemolytic streptococcus still holds first place. It will be remembered that Pasteur, in 1880, was the first to demonstrate streptococci in a case of puerperal infection, showing at that time what is now known to be the fact, that puerperal fever is in reality a wound infection. It is true that the possibility of endogenous infection is involved, and there is some strong evidence for it. However, the original idea of infection from the outside has dominated medicine since the days of Semmelweis, in 1843, and we believe that the great majority of observers still hold that puerperal fever is a wound infection, the offending organism gaining access from the outside.

As a matter of course, the source of the infection has been sought long and earnestly. In some cases, its origin is obvious, but in many, not. Cultures from healthy women during pregnancy indicate that the presence of hemolytic streptococci is comparatively rare, and auto-infection is considered by many to be uncommon, some even holding that it is inappreciable.

Infection by "spraying" from the throats of contacts has been suspected in this and other countries. A recent paper² discusses the matter in a convincing fashion, giving the histories of two outbreaks in two hospitals, one of which is classed as to some extent a "special

hospital," in the sense that no emergency cases are admitted, and the other a training school for midwives. In both, every antiseptic precaution was taken, except that no masks were worn.

In the first hospital, following one infection, a bacteriological examination showed hemolytic streptococci in the noses and throats of 6 out of 50 apparently healthy persons, 3 of whom were directly concerned in the delivery. Masks were then insisted upon during delivery, and later were extended to all postpartum nursing, with apparently good results.

In the second hospital, the outbreak began with a streptococcal infection in a "district" case. One pupil appears to have been the innocent cause of the infection of 5 "district" cases and also of her fellow nurses in the hospital. While the health of the nursing staff was excellent up to a certain date, two days after the first septic case in the hospital a nurse developed an infection of a finger, and within a fortnight 5 other nurses were laid up with septic fingers or sore throats, while 2 developed symptoms suggestive of scarlet fever, though this diagnosis was not made. In 12 remaining nurses examined for hemolytic streptococci, 6 were found to be positive. Masks were then ordered for all deliveries and postpartum treatments, and appear to have been the agents which cut off the source of infection.

The author of the paper mentioned gives a fair consideration to all aspects of the case, and draws the very conservative conclusion that enough evidence was collected to justify full investigation of throat carriers.

While the evidence is not conclusive, it is believed that sufficiently strong evidence has been brought forward to make the possible importance of spraying from streptococcal throats as the source of infection in puerperal infections a matter for careful investigation. Anything which offers hope of reducing the maternal mortality deserves the most careful consideration and study.

PRELIMINARY PROGRAM OF THE FIFTY-NINTH
ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION

Fort Worth, Texas, October 27-30, 1930

DELEGATES are urged to consult the Final Program, at the meeting, for information as to the exact time and place of sessions. The General Sessions and all other meetings will be held in the Hotel Texas. Morning sessions will be at 9:30; luncheon sessions at 12:30; afternoon sessions at 2:30; dinner sessions at 6:30; and evening sessions at 8:00.

GENERAL SESSIONS

First Session—Monday Evening

Addresses of Welcome:

THE HONORABLE WILLIAM BRYCE, Mayor, City of Fort Worth.
WALTER B. SCOTT, President, Fort Worth Chamber of Commerce.
THE HONORABLE DAN MOODY, Governor of the State of Texas.
JOHN W. BURNS, M.D., President, Texas State Medical Association.
M. E. GILMORE, M.D., President, Tarrant County Medical Society.
H. K. READ, M.D., President, Texas Association of Sanitarians.

Address of the President of the American Public Health Association. A. J. CHESLEY, M.D., State Health Officer, St. Paul, Minn.

The Health Problem in Mexico. RAFAEL SILVA, M.D., Chief of the Departamento de Salubridad Publica, Mexico City, Mex.

Reception and Dancing.

Second Session—Tuesday Evening

Reports of the Four Standing Committees of the Association:

Committee on Fellowship and Membership. *Chairman*, SALLY LUCAS JEAN, New York, N. Y.

Committee on Meetings and Publications. *Chairman*, C. C. YOUNG, D.P.H., State Department of Health Laboratories, Lansing, Mich.

Committee on Administrative Practice. *Chairman*, C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

A Study of Rural Health Work. A. W. FREEMAN, M.D., School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., and E. L. BISHOP, M.D., State Health Commissioner, Nashville, Tenn.

Seeing Cities through the Health Conservation Contest. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Committee on Research and Standards. *Chairman*, ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md.

Report on the White House Conference. WILLIAM F. SNOW, M.D., General Director, American Social Hygiene Association, New York, N. Y.

BARBECUE AND RODEO

Wednesday—4 P.M.

Third Session—Banquet—Thursday Evening

No Title. ARISTIDES AGRAMONTE, M.D., Professor of Bacteriology, University of Havana, Havana, Cuba.

The Cost of Public Health as a Public Investment. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Dancing.

SPECIAL SESSIONS

SYMPOSIUM ON MENINGITIS

LABORATORY, EPIDEMIOLOGY AND HEALTH OFFICERS SECTIONS

Monday Afternoon

Epidemiological Methods in the Control of Meningococcus Meningitis. WILLIAM H. PICKETT, M.D., State Department of Health, Lansing, Mich.

Experience of Meningitis Division of New York City Department of Health (Clinical and Bacteriological). JOSEPHINE NEAL, M.D., New York, N. Y.

Practical Problems in the Serum Therapy of Meningococcus Meningitis. A. B. WADSWORTH, M.D., State Department of Health, Albany, N. Y.

Epidemiological Study of 740 Cases and 376 Deaths from Meningococcus Meningitis in California. W. M. DICKIE, M.D., Secretary, State Board of Health, Sacramento, Calif.

An Epidemiological Study of 395 Cases of Meningococcus Meningitis. M. R. FRENCH, M.D., Health Department, Milwaukee, Wis.

Control Measures on Shipboard for Meningococcus Meningitis. J. C. GEIGER, M.D., University of California Medical School, San Francisco, Calif.

Discussion of all papers.

INTER-RELATION OF THE HEALTH OFFICER AND GENERAL PRACTITIONER TO PREVENTIVE MEDICINE

Wednesday Morning

Addresses by:

SHIRLEY W. WYNNE, M.D., DR.P.H., Commissioner of Health, New York, N. Y.

GORDON BATES, M.D., General Secretary, Canadian Social Hygiene Council, Toronto, Ont.

W. C. C. COLE, M.D., Children's Clinic, Detroit, Mich.

RALPH REYNOLDS, M.D., Assistant in Medicine, Stanford University, San Francisco, Calif.

W. H. ROSS, M.D., President, New York State Medical Society, Brentwood, N. Y.

GEORGE C. RUHLAND, M.D., Commissioner of Health, Syracuse, N. Y.

PSITTACOSIS

HEALTH OFFICERS AND LABORATORY SECTIONS

Thursday Morning

History and Distribution. GEORGE W. MCCOY, M.D., Director National Institute of Health, Washington, D. C.

Etiology. CHARLES KRUMWIEDE, M.D., Department of Health, New York, N. Y.

Pathology. RALPH DOUGALL LILLIE, M.D., National Institute of Health, Washington, D. C.

Discussion. R. H. RILEY, M.D., Director, State Department of Health, Baltimore, Md.

JOINT SESSIONS

FOOD, DRUGS AND NUTRITION AND CHILD HYGIENE SECTIONS

Monday Morning

Local and General Aspects of the Dental and Nutritional Problems in the Large City. HARRIS R. C. WILSON, D.D.S., Director of Mouth Hygiene, Board of Education, Cleveland, O.

Precise Evaluation of Light Therapy in Experimental Rickets. JOHN W. M. BUNKER, PH.D., Professor of Biochemistry and Physiology, and ROBERT S. HARRIS, Research Associate, Massachusetts Institute of Technology, Cambridge, Mass. (*Stereopticon Illustration.*)

Fatigue. No author.

Focal Infection. WESTON A. PRICE, D.D.S., Cleveland, O.

Soft Curded Milk: Nature's Food for Infants. R. L. HILL, M.D., Human Nutritionist, Utah State Agricultural College, Logan, Utah.

Comparative Dietary Studies of Mexican, Negro and White Children of Nursery School Age. JET C. WINTERS, PH.D., Director Nutrition Research, University of Texas, Austin, Tex.

CHILD HYGIENE, PUBLIC HEALTH EDUCATION AND PUBLIC
HEALTH NURSING SECTIONS*Tuesday Afternoon*

What Do Children Know about Health at Various Ages? DON W. GUDAKUNST, M.D., Director of School Health Service, Department of Health, Detroit, Mich.

Correlation Between the School's Medical Service and the Teaching of Health. No author.

Infantile Health Centers in the Capital of the Republic. MARIO TORROELLA, M.D., Director of Child Hygiene, Departamento de Salubridad Publica, Mexico City, Mex.

The Value of Psychiatric Service in a Visiting Nurse Program. RUTH GILBERT, R.N., Supervisor Mental Hygiene, Department of Health, Syracuse, N. Y.

Where and How Have the Best Plans Been Perfected for Developing a State-wide Program of Immunization and What Part Has the Public Health Nurse Taken? MARION SHEAHAN, R.N., Assistant Director, Division of Public Health Nursing, State Board of Health, Albany, N. Y.

PUBLIC HEALTH ENGINEERING AND FOOD, DRUGS AND
NUTRITION SECTIONS*Thursday Morning*

Progress in the Enforcement of the New York State Milk Code. C. A. HOLMQUIST, Director, Division of Sanitation, and W. D. TIEDERMAN, Chief, Bureau of Milk Sanitation, State Department of Health, Albany, N. Y.

The Milk Control Program in Texas. C. M. ROSSER, M.D., State Board of Health, Dallas, Tex., and FRED B. GREEN, V.M.D., Chief Milk Supervisor, State Board of Health, Austin, Tex.

Effect of Heat on Food Value of Milk. M. J. PRUCHA, and J. M. BRANNON, PH.D., University of Illinois, Urbana, Ill.

Present Status of Acidophilus Milk. WILLIAM D. FROST, DR.P.H., University of Wisconsin, Madison, Wis.; T. H. BUTTERWORTH and STEWART M. FARR, Laboratories of Brook Hill Farms, Genesee, Wis.

Relative Corrosiveness of Equipment by Dairy Products. J. H. SHRADER, PH.D., Director, Research Laboratory, National Dairy Products Corporation, Baltimore, Md.

Preliminary Report of Studies on Transformation of the Intestinal Flora Through the Feeding of Unfermented Acidophilus Milk. R. P. MYERS, PH.D., M. E. PARKER and LILLIAN W. CONN, Research Laboratory, National Dairy Products Corporation, Baltimore, Md.

PUBLIC HEALTH ENGINEERING AND INDUSTRIAL HYGIENE
SECTIONS

Thursday Afternoon

JOHN F. SKINNER, *Chairman*, Public Health Engineering Section, *Presiding*.

SYMPOSIUM ON ATMOSPHERIC POLLUTION

Introduction. ANTHONY J. LANZA, M.D., *Chairman*, Industrial Hygiene Section, Assistant Medical Director, The Metropolitan Life Insurance Company, New York, N. Y.

Engineering Phases of Industrial Hygiene. L. R. THOMPSON, M.D., Surgeon in charge, Office of Industrial Hygiene and Sanitation, U. S. Public Health Service, Washington, D. C.

The Medical Aspects of Atmospheric Pollution. T. C. TERRELL, M.D., Terrell Laboratories, Fort Worth, Tex.

The Amelioration of Atmospheric Pollution. HOWARD W. GREEN, Sanitary Engineer, Cleveland Health Council, Cleveland, O.

The Public Health Aspects of Atmospheric Pollution. C. A. SAPPINGTON, M.D., Director, Division of Industrial Health, National Safety Council, Chicago, Ill.

Discussion of all papers.

SECTION SESSIONS

LABORATORY

First Session—Wednesday Morning

Report of the Committee on Standard Methods. *Chairman*, E. O. JORDAN, Ph.D., University of Chicago, Chicago, Ill.

Laboratory Methods and Their Utilization in Milk Control. ROBERT S. BREED, Ph.D., State Agricultural Experiment Station, Geneva, N. Y.

The Gordon Precipitation Test for Smallpox. L. C. HAVENS, M.D., Director of Laboratories, State Board of Health, Montgomery, Ala.

The Results of Serological and Cultural Examination of Three Thousand Specimens of Blood. THOMAS F. SELLERS, Director, State Board of Health Laboratories, Atlanta, Ga.

Experimental Typhoid Carriers. A Study of Factors Affecting the Periodic Shedding of Organisms. LLOYD ARNOLD, M.D., Professor of Bacteriology, University of Illinois, Chicago, Ill., and THOMAS G. HULL, Ph.D., Director, State Board of Health Laboratory, Springfield, Ill.

Standardization of the Wassermann Reaction. PEDRO PEREZ GROVAS, M.D., Departamento de Salubridad Publica, Mexico City, Mex.

Immunization of Dogs Against Rabies by the One Injection Method. H. W. SCHOENING, D.V.M., Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

The Lethal Effects of Methyl Chloride on Laboratory Animals. JOHN L. WHITE, M.D., FRED O. TONNEY, M.D., and PAUL P. SOMERS, Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

Second Session—Thursday Afternoon

Report of the Committee on Abstracts in the Journal. *Chairman*, C. C. YOUNG, D.P.H., State Department of Health Laboratories, Lansing, Mich.

SYMPOSIUM ON UNDULANT FEVER

Identification of Strains of Brucella Group of Organisms. I. FOREST HUDDLESON, D.V.M., Michigan State College, East Lansing, Mich.

The Effects of Pasteurization on B. Abortus in Milk. CHARLES M. CARPENTER, PH.D., D.V.M., Albany Medical College, Albany, N. Y.

A Study of the Epidemiology of Undulant Fever. H. E. HASSELLTINE, M.D., U. S. Public Health Service, Washington, D. C.

Agglutins for B. Abortus in the Blood and Milk of Cows and the Use of the Agglutination Reaction in the Control of Certified Milk. JOHN F. NORTON, PH.D., and L. R. PLESS, Department of Health, Detroit, Mich.

Public Health Control of Infectious Abortion in Certified Milk. K. F. MEYER, M.D., George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

B. Abortus in Certified Milk. D. E. HASLEY, M.S., Detroit School of Medicine, Detroit, Mich.

HEALTH OFFICERS

First Session—Tuesday Morning

Public Health and the City Manager. O. E. CARR, City Manager, Fort Worth, Tex.

Mexican Immigrants. E. O. CHIMENE, M.D., City Health Department, Austin, Tex.

Texas-Mexico Border Health Problems. J. C. ANDERSON, M.D., State Health Officer, Austin, Tex.

Decrease of Tuberculosis in Mexico. SALVADOR BERMUDEZ, M.D., Departamento de Salubridad Publica, Mexico City, Mex.

Section Business.

Dinner Session—Tuesday Evening

The Health Officer of the Past. JAMES A. HAYNE, M.D., State Commissioner of Health, Columbia, S. C.

The Health Officer of the Present. No author.

The Health Officer of the Future. ARTHUR T. MCCORMACK, M.D., State Department of Health, Louisville, Ky.

VITAL STATISTICS

*First Session—Monday Morning**Announcements.*

Difficulties in Rural Registration Overcome Without Money.
 BUTLER TOOMBS, Director, Bureau of Vital Statistics, State Board of Health, Atlanta, Ga.

Report of the Committee to Aid Completion of the Registration Area. *Chairman*, LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Report of the Committee on Registration Affairs. T. F. MURPHY, M.D., *Acting Chairman*, Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

Physical Findings in New York City Continuation School Boys—An Element in the Vital Statistics of Adolescents. JEROME MEYERS, M.D., Department of Health, New York, N. Y.

Discussion. SELWYN D. COLLINS, PH.D., Associate Statistician, in Charge of the Office of Statistical Investigations, U. S. Public Health Service, Washington, D. C.

No Title. J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Discussion. FREDERICK L. HOFFMAN, LL.D., Consulting Statistician, Prudential Insurance Company of America, Newark, N. J.

*Second Session—Tuesday Morning**Section Business.*

No Title. MANUEL MARTINEZ BAEZ, M.D., In charge of Propaganda and Education, Departamento de Salubridad Publica, Mexico City, Mex.

Report of the Committee on Accuracy of Certified Causes of Death and Its Relation to Mortality Statistics and the International List. *Chairman*, HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y.

Report of the Committee to Coöperate with the National Safety Council in Preparing Forms for Additional Information Regarding Accidents. *Chairman*, W. THURBER FALES, SC.D., State Registrar, State Board of Health, Montgomery, Ala.

The Accident Problem in Kansas. EARLE G. BROWN, M.D., Executive Health Officer, State Board of Health, Topeka, Kans.

Woman's Part in the Safety Campaign. GEORGE H. VAN BUREN, Supervisor, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

Third Session—Thursday Morning

Completion of the Registration Area. LOUIS I. DUBLIN, PH.D., Statistician, Metropolitan Life Insurance Company, New York, N. Y.

Neonatal Mortality as Affected by Mother's Age and Obstetrical Care. ELBRIDGE SIBLEY, Statistician, State Department of Public Health, Nashville, Tenn.

Discussion. BLANCHE M. HAINES, M.D., Director, Maternity and Infancy Division, U. S. Children's Bureau, Washington, D. C.

Mortality from Puerperal Septicemia in the United States During Recent Years. GAIVUS E. HARMON, M.D., Department of Hygiene and Bacteriology, School of Medicine, Western Reserve University, Cleveland, O.

Report of the Committee on Proper Allocation of Records. *Chairman*, J. V. DEPORTE, PH.D., Director, Division of Vital Statistics, State Department of Health, Albany, N. Y.

Report of the Committee on Joint Causes of Death. *Acting Chairman*, T. F. MURPHY, M.D., Chief Statistician for Vital Statistics, Bureau of the Census, Washington, D. C.

Fourth Session—Thursday Afternoon

Hospital Statistics. E. H. LEWINSKI CORWIN, PH.D., Academy of Medicine, New York, N. Y.

Excess Mortality from Non-respiratory Causes During Influenza Epidemics. SELWYN D. COLLINS, PH.D., Associate Statistician, in Charge of the Office of Statistical Investigations, U. S. Public Health Service, Washington, D. C.

An Old Life Table or Rate Survivorship Table for New York City for the Years 1801-05. CHARLES BOLDUAN, M.D., Director of Health Education, Department of Health, New York, N. Y.

Report of the Committee on Public Health Climatology. *Chairman*, E. W. KOPF, Metropolitan Life Insurance Company, New York, N. Y.

No Title. LOWELL J. REED, PH.D., Department of Biometry and Vital Statistics, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

No Title. SHIRLEY W. WYNNE, M.D., DR.P.H., Commissioner of Health, New York, N. Y.

PUBLIC HEALTH ENGINEERING

First Session—Tuesday Morning

Waterborne Typhoid Still a Menace. ABEL WOLMAN, Chief Engineer, State Department of Health, Baltimore, Md., and ARTHUR E. GORMAN, Wallace & Tiernan Co., Inc., Newark, N. J.

The Effect of Taste Elimination Treatments on the Bacterial Quality of the Water (Report of the Committee on Water Supply). *Chairman*, JOHN R. BAYLIS, Filtration Chemist, Department of Public Works, Chicago, Ill.

SYMPOSIUM ON PUBLIC HEALTH ENGINEERING PROBLEMS IN THE
SOUTHWEST

Sanitary Features of Irrigation Projects. JANE H. RIDER, Director
State Laboratory, Tucson, Ariz.

Plan of Organization of a Federal Department of Drainage
Works. JOAQUIN M. SEGURA, Sanitary Engineer, Departamento de
Salubridad Publica, Mexico City, Mex.

Control of Cross-Connections in Texas Cities. W. N. DASHIELL,
City Sanitary Engineer, Fort Worth, EDGAR WHEDBEE, City Water
Department, Dallas, and J. A. SAULS, City Water Department, Hous-
ton, Tex.

Sanitary Control of Underground Water Supplies in Texas.
CHESTER COHEN, State Department of Health, Austin, Tex.

Emergency Sanitary Measures Following a Flood Disaster.
PAUL S. FOX, Chief, Division of Sanitary Engineering and Sanitation,
Bureau of Public Health, Santa Fe, N. M.

Progress in Disaster Relief Preparedness Programs (Report of the
Committee on Disaster Relief). *Chairman*, E. L. FILBY, Chief Engi-
neer, State Board of Health, Jacksonville, Fla.

Second Session—Tuesday Afternoon

SYMPOSIUM ON MALARIA CONTROL

The Increase in the Malaria Incidence—a Challenge. JOHN A.
FERRELL, M.D., Associate Director, International Health Division,
Rockefeller Foundation, New York, N. Y.

Cost of Malaria Control. J. A. LEPRINCE, Senior Sanitary Engineer,
U. S. Public Health Service, Memphis, Tenn.

Promoting Malaria Control Programs (Report of the Committee on
Insects and Rodents). *Secretary*, G. H. HAZELHURST, Chief Sanitary
Engineer, State Board of Health, Montgomery, Ala.

Screen and Mosquito Proofing as Elements in a Malaria Control
Program. H. R. FULLERTON, C.E., Department of Public Health,
Nashville, Tenn.

The Sanitary Significance of River Flood Control (Report of the
Committee on Waterways Pollution). *Chairman*, ERNEST R. BOYCE,
Chief Engineer, State Board of Health, Lawrence, Kans.

The Promotion of Environmental Sanitation (Report of the Com-
mittee on Environmental Sanitation). *Chairman*, V. M. EHLERS, Chief
Engineer, State Department of Health, Austin, Tex.

Eliminating Health Hazards in Plumbing (Report of the Joint Com-
mittee on Plumbing). *Chairman*, JOEL I. CONNOLLY, Chief, Bureau of
Sanitary Engineering, Department of Health, Chicago, Ill.

Recent Developments in Sewage Disposal (Report of the Com-
mittee on Sewage Disposal). *Chairman*, LANGDON PEARSE, Sanitary
Engineer, The Sanitary District of Chicago, Chicago, Ill.

Significant Items on Pasteurization of Milk (Report of the Com-
mittee on Milk Supply). *Chairman*, H. A. WHITTAKER, Director,
Division of Sanitation, State Department of Health, Minneapolis, Minn.

Shell Fish Sanitation Studies (Report of the Committee on Shell Fish Supply). *Chairman*, H. D. PEASE, M.D., Pease Laboratories, New York, N. Y.

Detailed Committee Reports will be available in mimeographed form to those present, but practically all will be delivered by the Chairmen in condensed form to provide ample time for discussion.

Sunday, October 26

All day inspection trip for Conference of State Sanitary Engineers and *all visiting engineers*, leaving Fort Worth by automobile 9.00 A.M., arriving Dallas 10.00 A.M. Inspection of Dallas's new water purification plant and old sewage purification plant, ending with complimentary visit to the State Fair of Texas where the group will have access to a variety of entertainment.

Tuesday, October 28—6.30 P.M.

Public Health Engineering Section and Conference of State Sanitary Engineers. Annual Engineers Stag Dinner Party at Hotel Texas.

Wednesday, October 29

Joint Inspection Trips—Public Health Engineering Section and Conference of State Sanitary Engineers:

9.30 A.M.—Fort Worth Water Purification and Sewage Treatment Plants.

Swift and Armour Packing Plants.

Complimentary Luncheon.

2.00 P.M.—Cleburne Sewage Works.

INDUSTRIAL HYGIENE

Luncheon Session—Monday

Presiding: ANTHONY J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

First Session—Monday Afternoon

Chairman's Address. ANTHONY J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Human Relationships on Railroads. J. N. REDFERN, Manager, Relief, Medical, Employment and Pension Department, Chicago, Burlington & Quincy Railroad Company, Chicago, Ill.

Discussion

Abnormal Mental States Among Industrial Workers. EMERSON NORTH, M.D., Director, The Mental Hygiene Clinic, Cincinnati, O.

Discussion.

Industrial Medical Experiences in South Africa. J. G. CUNNINGHAM, M.D., Provincial Board of Health, Toronto, Ont.

Discussion.

Section Business and Election of Officers.

Second Session—Tuesday Afternoon

Lead Poisoning in the United States During 1929-1930 (Report of the Committee on the Status of Lead Poisoning). *Chairman*, EMERY R. HAYHURST, M.D., Professor of Hygiene, Ohio State University, Columbus, O.

Discussion.

Nomenclature in Occupational Diseases (Report of the Committee on Standard Practices in the Problem of Compensation of Occupational Diseases). *Chairman*, HENRY H. KESSLER, M.D., Medical Director, Occupational Disease Clinic, State Department of Labor, Newark, N. J.

Discussion.

Developments in the Field of Industrial Fatigue (Report of the Committee on Industrial Fatigue). ANTHONY J. LANZA, M.D., Assistant Medical Director, Metropolitan Life Insurance Company, New York, N. Y.

Discussion.

The Newer Volatile Solvents (Report of the Committee on Volatile Solvents). *Chairman*, ELIZABETH B. BRICKER, M.D., Chief of Hygiene and Sanitation, Department of Labor and Industry, Harrisburg, Pa.

Discussion.

Toxicity of Benzol Hemologues. HENRY FIELD SMYTH, M.D., University of Pennsylvania, Philadelphia, Pa.

*Discussion.**Section Business.**Third Session—Thursday Morning*

Industrial Medicine in Mexico. JOAQUIN M. SEGURA, M.D., Sanitary Engineer, Departamento de Salubridad Publica, Mexico City, Mex.

Discussion.

Fungus Infection of the Skin of Industrial Workers. ROBERT T. LEGGE, Ph.G., M.D., Professor of Hygiene, University of California, Berkeley, Calif.

Discussion.

Cardio Vascular Lesions Among One Thousand Industrial Machine Operators. A Report of One Thousand Physical Examinations of Machine Operators. WILLIAM A. MUHLBERG, M.D., Medical Director, The Union Central Life Insurance Company, FLOYD P. ALLEN, M.D., Secretary, The Heart Council of Greater Cincinnati, and BLEECKER MARQUETTE, Secretary, The Public Health Federation, Cincinnati, O.

Discussion.

Occupational Nystagmus. CAREY P. McCORD, M.D., Medical Director, The Industrial Health Conservancy Laboratories, Cincinnati, O.

Discussion.

FOOD, DRUGS AND NUTRITION

First Session—Tuesday Afternoon

Report of the Committee on Fish and Shell Fish. *Acting Chairman*, A. C. HUNTER, PH.D., In Charge, Bacteriological Unit Food Control Laboratory, Food, Drug and Insecticide Division, U. S. Department of Agriculture, Washington, D. C.

Some Observations on Enforcement of Food and Drug Laws in Texas, Including Ginger Poisoning. E. J. LEMAY, State Department of Health, Austin, Tex.

Newer Knowledge on Botulism and Mussel Poisoning. K. F. MEYER, M.D., George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

SYMPOSIUM ON OCCURRENCE OF MINUTE AMOUNTS OF METAL IN FOODS

The Use of Metallized Foods. PROF. J. L. MCGHEE, Emory University, Atlanta, Ga.

Iodine in Nutrition WILLIAM WESTON, M.D., South Carolina Food Research Committee, Columbia, S. C.

Effect of Metals Derived from Cooking Utensils on the Health of the Consumer. WALTER H. EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

Discussion. F. C. BLANCK, PH.D., Food Research Division, U. S. Bureau of Chemistry and Soils, Washington, D. C.

Report of the Committee on Meat and Meat Products. *Acting Chairman*, PAUL E. HOWE, PH.D., Senior Biological Chemist in Charge, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

Second Session—Wednesday Morning

Report of the Committee on Cereals and Their Products. *Chairman*, F. C. BLANCK, PH.D., Food Research Division, U. S. Bureau of Chemistry and Soils, Washington, D. C.

Report of the Committee on Nutritional Problems. *Chairman*, PROF. HENRY C. SHERMAN, Department of Chemistry, Columbia University, New York, N. Y.

A Study of the Diets of Federal Prisoners. PAUL E. HOWE, PH.D., Senior Biological Chemist in Charge, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C.

The Nutritive Values of Processed Milks. JAMES A. TOBEY, PH.D., Director Health Service, The Borden Company, New York, N. Y.

Some Observations on Musty Eggs. PROF. MAX LEVINE and D. Q. ANDERSON, Iowa State College, Ames, Iowa.

Report of the Committee on Fruits and Vegetables. *Acting Chairman*, WALTER H. EDDY, PH.D., Teachers College, Columbia University, New York, N. Y.

Report of the Committee on Milk and Dairy Products. *Chairman*, WILLIAM B. PALMER, Executive Officer, Milk Inspection Association of the Oranges, Orange, N. J.

Luncheon Session—Wednesday

CHILD HYGIENE

First Session—Tuesday Morning

PRACTICAL APPLICATION OF THE COMMUNITY CHILD HYGIENE PROGRAM
The Infant Before, During and After Birth (From early pregnancy through first year of life). RICHARD A. BOLT, M.D., Director, Cleveland Child Health Association, Cleveland, O.

The Community Health Program as It Applies to the Child from One to Six Years of Age. H. N. BARNETT, M.D., Chief, Division of Child Hygiene, State Department of Health, Austin, Tex.

The Community Health Program As It Applies to the Child from Six Years to Adolescence. WALTER H. BROWN, M.D., Professor of Hygiene, Department of Physical Education and Hygiene, Stanford University, Palo Alto, Calif.

The Adolescent Age. No author.

PUBLIC HEALTH EDUCATION

First Session—Monday Morning

What Mr. Average Citizen Knows and Does About Health. HOWARD W. GREEN, Sanitary Engineer, Cleveland Health Council, Cleveland, O.

What He Should Know and Do. C.-E. A. WINSLOW, DR.P.H., Yale University, New Haven, Conn.

The Work of the Health Department of Mexico in Relation to Health Education. MANUEL MARTINEZ BAEZ, M.D., In charge of Propaganda and Education, Departamento de Salubridad Publica, Mexico City, Mex.

Dinner Session—Monday Evening

Closed Session—For Members and Fellows of Section only
Section Business.

Luncheon Session—Tuesday

What an Extension Division of a University Can Do Along the Lines of Public Health Education. BERTHA ASHBY, University of Oklahoma, Norman, Okla.

Discussion. JEAN M. PINCKNEY, University of Texas, Austin, Tex.

Second Session—Thursday Morning

Hazards of Commercial Health Advertisements. BLEECKER MARQUETTE, Executive Secretary, Public Health Federation, Cincinnati, O.

What Technic of Commercial Advertisers May Be Used Effectively by the Health Worker? W. W. BAUER, M.D., Health Officer, Racine, Wis.

Discussion. HAVEN EMERSON, M.D., Department of Public Health Administration, Columbia University, New York, N. Y., and J. C. FUNK, Director of Health Education, State Department of Health, Harrisburg, Pa.

PUBLIC HEALTH NURSING

First Session—Monday Afternoon

The Relation of Official and Non-Official Groups Administering Public Health Nursing Service in the Following Respects:

- a. Joint Staff Education Program.
- b. Sharing of Specialized Supervisors such as Nutrition and Mental Hygiene.
- c. Division of Responsibility to Avoid Duplication in Program of Work in Families.

ELIZABETH W. HOLT, R.N., Director of Nursing, Visiting Nurse Association, Dayton, O.

Discussion.

How Can We Teach Public Health Agents, Particularly the Rural Nurse, to Present Her Public Health Needs and Results in an Interesting Manner to Appropriating Bodies with the Object of Obtaining Increased Support? RUTH WOOD, R.N., Director, Maternity Center Association, Brooklyn, N. Y.

How To Secure and Use Advisory Committees for Official and Non-Official Agencies. NETTA FORD, R.N., Visiting Nurse Association, York, Pa.

Nursing Service and Health Education Must Dovetail to Have an Effective Health Program. The Nurse's Part in Arousing Interest and Suggesting Methods for Results. KATHARINE HAGQUIST, R.N., State Department of Health, Austin, Tex.

Second Session—Tuesday Morning

The Prevention of Cancer as a State-Wide Program and the Nurse's Responsibility in This Program. JOSEPH COLT BLOODGOOD, M.D., Chairman, Maryland Cancer Committee, Baltimore, Md.

Discussion.

Problems Equally Trying to Health Officer and Nurse in the Administration of Small Town or Rural Health Work. Plans that Have Been Effective. The Kind of Administration that Develops the Nurses and Makes it Possible for Them to get Effective Results. JESSIE L. MARRINER, R.N., Director, Bureau of Health Hygiene, and Public Health Nursing, State Board of Health, Montgomery, Ala.

How the Nursing Staff of a Well Organized County Health Department is Directed and Obtains Effective Results through Supervision. No Author.

Discussion on Administrative Practice in States, Counties and Cities. What are the Nurse's Responsibilities and How Should She Correlate Her Activities with Other Health Agencies? MYRA CLOUDMAN, R.N., American Red Cross, St. Louis, Mo.

The Work of the Visiting Nurse in Mexico. MARIO TORROELLA, M.D., Director of Child Hygiene, Departamento de Salubridad Publica, Mexico City, Mex.

EPIDEMIOLOGY

First Session—Monday Morning

SYMPOSIUM ON TYPHOID FEVER

Water-Borne Typhoid at Seneca Falls. F. W. SEARS, M.D., Syracuse. N. Y.

Epidemiological Features of Typhoid Fever in Richmond, Virginia. A. W. FREEMAN, M.D., School of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md.

Olean City Epidemic of Typhoid Fever in 1928. A. S. DEAN, M.D., State District Health Officer, Jamestown, N. Y.

Typhoid Fever in Knoxville, Tenn. (second paper) with special reference to the significance of findings in a detailed sanitary survey of the city. WILLIAM H. ENNEIS, M.D., Knoxville, Tenn.

Discussion of papers on Typhoid Fever.

Second Session—Wednesday Morning

Incidence of Partial Paralysis. H. C. STEWART, M.D., and E. L. BISHOP, M.D., State Department of Health, Nashville, Tenn.

Incidence of So-called "Jake" Poisoning in Oklahoma City and Vicinity. DAVID T. BOWDEN, M.D., Director of Laboratories, State Department of Public Health, Oklahoma City, Okla.

Discussion.

Administrative Aspects of Epidemiology. GEORGE H. RAMSEY, M.D., Johns Hopkins University, Baltimore, Md.

Discussion.

Observations on the Result of Immunization Against Diphtheria in Children upon Case Incidence and Mortality from this Disease. C. H. KINNAMAN, M.D., Topeka, Kans.

Discussion.

MEETINGS OF OTHER ORGANIZATIONS DURING THE CONVENTION

American Association of School Physicians. Program to be Announced.
International Society of Medical Health Officers joint with the American Association of School Physicians. Program to be announced.
Association of Women in Public Health. Program to be announced.

Conference of State Sanitary Engineers (See Public Health Engineering Section Program).

Texas Association of Sanitarians. Program to be Announced.

1930 European Delegation. Dinner—Monday Evening.

Delta Omega. Dinner—Wednesday Evening.

PRELIMINARY PROGRAM

SCIENTIFIC SESSIONS IN MEXICO CITY

Monday Morning, November 3

Address of Welcome. RAFAEL SILVA, M.D., Chief of the Departamento de Salubridad Publica, Mexico City, Mex.

Reply to Address of Welcome. A. J. CHESLEY, M.D., President, American Public Health Association; HUGH S. CUMMING, M.D., Surgeon General, U. S. Public Health Service, Washington, D. C.; and J. C. ANDERSON, M.D., State Health Officer, Austin, Tex.

History of Health in Mexico. ULISES VALDES, M.D., Secretary General, Departamento de Salubridad Publica, Mexico City, Mex.

Local Public Health Work. MIGUEL BUSTAMANTE, M.D., Director Health Unit, Vera Cruz, Mex.

Display of Film Showing Public Health Work in Mexico.

Tuesday Morning, November 4

Address. W. S. RANKIN, M.D., Chairman, Executive Board, American Public Health Association, Duke Endowment, Charlotte, N. C.

Address. B. J. LLOYD, M.D., Pan American Sanitary Bureau, Washington, D. C.

Safeguarding a City Milk Supply. H. V. CARDONA, D.V.M., Supervisor of Milk Sanitation, Department of Public Health and Welfare, Fort Worth, Tex.

For information regarding railroad fares to Fort Worth, hotel rates in Fort Worth, and full details of the Mexico City post convention tour, consult June and July issues of the American Journal of Public Health.

ASSOCIATION NEWS

FIFTY-NINTH ANNUAL MEETING FORT WORTH, TEXAS *October 27-30, 1930*

SOME MEMBERS OF THE LOCAL COMMITTEE

A. H. FLICKWIR, M.D.
*Director Public Health and
Welfare, Fort Worth, Tex.*

J. C. ANDERSON, M.D.
*State Health Officer,
Austin, Tex.*

MRS. HENRY B. TRIGG
*Chairman, Women's Enter-
tainment Committee,
Fort Worth, Tex.*

WELCOME TO TEXAS

MRS. O. E. CARR

Member of Women's Entertainment Committee, Fort Worth, Texas

ROTARIANS seem to have recognized earliest the benefits of close association and travel. Every separate organization of that leadership has become a "know your own country" enthusiast. The American Public Health Association has set its face toward Texas for its late October Annual Meeting.

There are loyal members who will follow wherever the Association elects to go. There are other members who will say: "It is a long trip and a hard one and just why should I make a special effort to go to Texas? If it were New York City, now, etc., . . . if it were Denver, etc., etc., . . . or if it were San Francisco, etc., etc., etc. . . ." But the

American Public Health Association is going to Texas; they reiterate it in a most matter of fact way. If the individual is from New York City he is not anticipating much, for does not civilization reach the positive dead line at Buffalo? And Texas, particularly, has but wigwams, Indians and cow-punchers. Texas smiles quietly in her sleeve; too big for jealousy, too generous for fault-finding, hospitably waiting for all of the world, and the American Public Health Association in particular, to come, to find, to love, to hold a unique memory close forever.

Some of the members will travel south by automobile. They will ride for miles over well conditioned roads toward Fort Worth, the shadowy outlines of her skyscrapers appearing finally on the horizon, mystic as mirage, and dim as the fabled city of Camelot. It is the end of a long journey and the wayfarer will find peace, a good hotel, and the best and cheapest food in the land.

It is October in Texas; there is not a trace of frost in the air, for it is not yet time to think of winter. If the month were May a short excursion into the byways would reveal the lavish array of Texas wild flowers—the Blue-bonnet the queen of them all. If it were July the watermelons would be coming in by the truck load—big, juicy, sweet and luscious beyond description. There are those who having once tasted real Texas melon have thereafter refused the delicacy elsewhere. But it is October! The pecans, native to this region, and the big paper-shelled variety are almost ripe now. Citrus fruits and vegetables are shipped in every day from the Rio Grande Valley and from the Winter Garden regions of Texas. Yellow-legged chickens are cooked in regiments every day by chefs with personality. Fort Worth and this delicious southern chicken will always loom large in memory. The spirit of hospitality is evident in the various clubs. Many men's clubs

there are and one of the most delightful Woman's Clubs in the country.

The most wonderful physiological fact about Fort Worth is the rapidity of the growth of the city. In 1920, the population was 103,000; in 1930, it is reaching for the 200,000 mark. Just a few miles from Fort Worth lies Lake Worth, probably the largest artificial body of water in Texas. It was designed by the City of Fort Worth for a water supply. Two more larger lakes are to be built to supplement it.

We have said that Texas was different, yet it is hard to put the difference in words. For instance, the sun goes down and night comes to Texas, as she does all over the world. There is white magic in Texas nights. The cares of the day go far away. The heavens come down very near and the stars are very bright. The spirit is reborn; romance blooms again; and the dreams which were born of youth's inexperience return with even greater allure.

Texas is a land of history. Coronado in his search for the fabled cities of gold probably crossed the site of Fort Worth in 1541. The state has been under five flags—five different types of government. The state produces oil, cattle, wheat, corn and cotton. Of late, manufacturing is developing rapidly.

Texas has sacred ground. Men lift their hats as they pass the Alamo—that quiet shrine, where men died for Texas liberty.

It may be that this past history and the traditions of Texas are the means of stimulating in this Southwest a growth of creative effort, which is manifesting itself in the composition of music, poetry and painting.

In Fort Worth and Texas generally, flying is making phenomenal progress, the climate being conducive to its development.

Texas is the last great frontier. It is hard to realize among the skyscrapers of Fort Worth that just a few hours away

hunting for game is still a possibility. Turkey and deer may be found west of Menard, and in the head waters of the San Saba a forty-seven and one-half pound catfish was landed only this summer—and there are more fish in the San Saba.

In Texas, the distances are vast and the thought of man wanders far. Almost every Texan knows a little of geology. Oil has its lessons. The bit that grinds its way toward the golden flow passes sand after sand that was

once sea floor. Fossil deposits have yielded wonderful results. In the Public Library of Fort Worth may be seen the tusks and cranium of a mastodon, thousands of years of age.

Yes, Texas is different. So different, that once here, man would live his life within the state boundary. Here are found all that round out life—friends, change, adventure, variety of climate, desirable pursuits, and the things that dreams are made of. Where can man find more?

WOMEN'S ENTERTAINMENT COMMITTEE

MRS. HENRY B. TRIGG

Chairman

THE chairman of the Local Committee has appointed a sub-committee to have charge of the entertainment for the ladies. This, of course, will include the women members of the Association and the wives and daughters of members.

The committee of women has planned several entertainment features that we hope will be of interest to our guests. Among these will be a ride over the city and adjacent country, which is indeed very picturesque in late October, and a musical tea at the Woman's Club. Fort Worth is very proud of its Woman's Club building, a most beautiful structure, located on one of our most attractive streets, Pennsylvania Avenue, and owned and supported by the women's clubs of this city. Naturally, it is the center of women's activities.

The women are, of course, invited to the barbecue and rodeo, the ride to Lake Worth, the annual banquet, and the dance to be given on the evening of the opening exercises.

The weather in Fort Worth in October is delightful for golf and the city has many country clubs and two municipal courses which will be thrown open for the use of our guests. Mrs. Pauline

MRS. PAULINE STRIPLING FRENCH

Stripling French, at one time woman golf champion of Texas, and one of our most noted golf enthusiasts, will have charge of this feature of the entertainment. Mrs. French will see that those interested in golf are furnished transportation and that arrangements are made for them to play. She would like very much to have the women bring their handicaps with them.

Automobiles will be available for those that would like to visit the health centers, universities, and other places of interest in the city, or perhaps look up some friend in Fort Worth. In other words, the committee of women will endeavor to do everything possible to make your stay in Fort Worth enjoyable

in order that you may remember it as one of the happiest occasions connected with the Annual Meetings of the American Public Health Association. We desire that our guests may feel that Fort Worth is truly typical of southwestern hospitality, for which it is known throughout the United States.

INVITATION TO VISIT SAN ANTONIO

An invitation has been extended by Dr. W. D. King, Health Officer of San Antonio, to stop over in that city on the way to Mexico City. This invitation has been officially authorized by the

City Health Board, Bexar County Medical Society, and the Auxiliary of the Bexar County Medical Society. Guests will be entertained at luncheon, October 31, and a sight-seeing trip has been planned.

NEW MEMBERS

Health Officers Section

G. A. Ashbaugh, M.D., Rocky Ford, Colo., Otero County Health Officer
A. Bossinotte, M.D., Matane, P. Q., Health Officer, Matane County Health Unit
Enoch M. Buckner, Dayton, Tenn., Sanitary Inspector, Rhea-Meigs County Health Unit
David D. Carr, M.D., LaFayette, Ala., County Health Officer
Arthur Caux, M.D., Lotbiniere, P. Q., Medical Officer of Health
Eliphalet A. Cornell, Sault Ste. Marie, Mich., Health Officer
Frederick U. Davis, M.D., Faribault, Minn., Health Commissioner
Judson D. Dowling, M.D., Birmingham, Ala., County Health Officer
J. Cyril Eby, M.D., Plaquemine, La., Director, Iberville Parish Health Unit
Edgar H. Hand, M.D., Charlotte, N. C., Assistant Health Officer, Mecklenburg County
Marie A. Harrison, R.N., Maplewood, N. J., Health Officer
Matthew J. Keough, M.D., Cohoes, N. Y., Health Commissioner
G. W. Luckey, M.D., Fort Worth, Tex., Assistant Director, Public Health and Welfare
Peel M. Payne, M.D., Napoleonville, La., Director, Assumption Parish Health Unit
Gerard C. Unrein, M.D., Hays, Kans., Ellis County Health Officer
Ludwig C. Yen, M.D., Nanking, China, Director, Department of Medical Administration (Assoc.)

Laboratory Section

Paul Eaton, M.D., Jacksonville, Fla., Director, Bureau of Laboratories, State Board of Health

James C. Hofmann, Topeka, Kans., State Bacteriologist, Public Health Laboratory
Newton W. Larkum, Ph.D., Lansing, Mich., Immunologist, State Department of Health
Eloy B. Moreno, Laredo, Tex., Milk and Dairy Inspector
Charles Paley, B.S., New York, N. Y. (Assoc.)
William O. Pauli, M.D., Cincinnati, O. (Assoc.)
Jack Wyatt, Amarillo, Tex., City Chemist

Public Health Engineering Section

Ashley G. Classen, Austin, Tex., Sanitary Engineer, Western Metal Manufacturing Co.
H. R. F. Helland, San Antonio, Tex., Consulting Sanitary Engineer
Bluford W. Jackson, Hammond, Ind., Municipal and Industrial Water Chemist
Mark B. Owen, Dearborn, Mich., Supt., Public Works and Engineering

Industrial Hygiene Section

Muriel B. Kingsley, B.S., Chicago, Ill., Health Education Secretary, Chicago Y. W. C. A.
Jessie B. Love, R.N., Van Lear, Ky., General Industrial Educational Program (Assoc.)
Zelma Rice, Fort Worth, Tex., City Industrial Hygiene Staff

Food, Drugs and Nutrition Section

E. E. Waters, Waco, Tex., Supt., Borden's Milk Company
Arthur H. Williamson, D.V.M., Charlotte, N. C., Supervisor, Dairy Sanitation, Health Department

Child Hygiene Section

- Lucile S. Blachly, M.D., Jacksonville, Fla., Director, Bureau Child Hygiene
 Anne Douglass, R.N., Houston, Tex., Supervising Nurse, Harris County Red Cross Public Health Nursing Service
 Mrs. May Fair, Sherman, Tex., School Nurse, City Schools
 Mary Kennedy, R.N., Houston, Tex., Health Supervisor, DePelchin Faith Home
 Emma G. Shannon, R.N., Fort Worth, Tex., Public School Nurse

Public Health Education Section

- Manuel M. Baez, M.D., Mexico, D. F., In charge hygienic education
 Mary L. Boillin, Clarksville, Tenn., Director, Department of Physical and Health Education, State Teachers College, Fredericksburg, Va.
 Mrs. S. I. Bolton, R.N., Nashville, Tenn., Exec. Secy., Davidson County Anti-Tuberculosis Association
 John E. Burke, M.D., Schenectady, N. Y., Director, Health Education
 Terence F. Cunneen, LL.B., Washington, D. C., Manager, Insurance Dept., Chamber of Commerce of United States (Assoc.)
 Patrick H. Fleming, M.D., St. Martinville, La., Director, St. Martin Parish Health Unit
 Jacob L. Lochner, Jr., M.D., Albany, N. Y., Assistant Medical Inspector, City Public Schools
 John O. McReynolds, M.D., Dallas, Tex. (Assoc.)
 Ira O. Park, M.D., Union City, Tenn., Medical Advisor, and Associate Editor *Babyhood*
 William H. Phipps, D.P.H., Kansas City, Mo. (Assoc.)
 Ralph A. Reynolds, M.D., San Francisco, Calif. (Assoc.)
 N. F. Williams, D.V.S., Fort Worth, Tex., State Veterinarian

Public Health Nursing Section

- Addie Alexander, R.N., Ballinger, Tex., County Health Nurse
 Christina Anderson, R.N., New York, N. Y., Supervisor of Nurses, Henry Street Visiting Nurse Association
 Thelma M. Bailey, R.N., Fort Worth, Tex., Public Health Nurse, City Staff
 Helen M. Bartholomew, R.N., Circleville, O., Pickaway County Public Health Nurse

- Ada L. Clark, Fort Worth, Tex., City Public Health Nurse
 Vella M. Custer, Fort Worth, Tex., Public Health Nurse, City Staff

FORT WORTH HOTEL RESERVATIONS

THE attention of delegates to the Fort Worth Annual Meeting is called to the fact that there is a shortage of single rooms in the headquarters hotel.

The Hotel Committee ask that reser-

vations for single rooms or other accommodations be sent in as soon as possible. They would appreciate an indication as to whether delegates will be willing to share rooms with others during the convention.

A complete list of Fellows and Members of the American Public Health Association, as of August 1, 1930, will be published in the October issue of the Journal.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Nursing Technic in Minneapolis—Dr. J. A. Myers of Minneapolis, in a paper (in press) presented before the nurses associations recent meeting in Milwaukee, emphasized the importance of strict contagious disease technic in the nursing of tuberculosis, directed primarily toward the protection of the nurse. The project is under way in Minneapolis to establish in the contagious building of the Minneapolis General Hospital, in co-operation with the Minneapolis Health Department, a 20-bed ward where student nurses are to be given strict contagious disease technic training in tuberculosis nursing. It is believed that this is a forward step in nursing technic for a general hospital and it is hoped that the demonstration will be of value to general hospitals throughout the country in teaching this important subject for the safeguarding of the health and lives of nurses engaged in the nursing of tuberculous patients.—F. E. Harrington, M.D., Health Commissioner, Minneapolis, Minn.

Undulant Fever—During the past year investigations have been carried on by the U. S. Public Health Service along two lines. Dr. Hardy, in Iowa, has studied approximately 200 cases occurring in that state in 1929 which, added to those previously investigated, provides a total of 375 cases for his epidemiologic study. Dr. Hasseltine has investigated 109 cases in 14 different states. Of 442 cases for which epidemiologic data are available, 198 are placed in the milk group, having occurred in individuals who have not been exposed to livestock. There are 200 cases in the farm group, people living in

the country who have direct contact with livestock. There are 44 cases in the meat group, urban cases having direct contact with livestock or carcasses.

There have been 13 cases in children under 10 years of age. The greatest incidence has been in the age group 35 to 44. Simpson has collected 1,305 cases in the United States.

Pasteurization of milk is an effective means of protecting against milk-borne infection. Arnold, in the January issue of the *Health Messenger* of the Illinois State Board of Health, reported that 140° F. for 40 minutes was required to kill certain strains of *Brucella abortus*. He did not, however, give any details, and the temperature which he used is 2° or 3° below the standard pasteurization temperature. The epidemiologic studies indicate that where milk has been a factor in the spread of infection, the supply had not been pasteurized. In two cities, Frederick, Md., and Waycross, Ga., ordinances have been passed requiring that all milk be pasteurized. The immediate factor stimulating the passage of such ordinances was outbreaks of undulant fever due to raw milk.

Undulant fever can also be contracted by means of transmission other than milk. Contact with infected animals, particularly infected hogs, may result in infection. While the serological examination of livestock is a practicable method of attacking the problem of undulant fever, for the present at least, we must rely upon the education of those whose occupation subjects them to the hazard to guard against contact infections, and upon pasteurization to prevent milk-borne cases. Pasteurization

of the milk renders it safe and takes care not only of undulant fever but of all other communicable diseases transmitted by milk.—H. E. Hasseltine, Recent Progress in Studies of Undulant Fever, *Pub. Health Rep.*, 45, 1660 (July 18), 1930.

Diphtheria Prevention in New York—The total number of children immunized against diphtheria during the first 6 months of 1930 is less than for the same period of the preceding year when 124,000 children were immunized. This indicates the great difficulty in reaching people in a large city. The campaign has yielded valuable results with low figures in cases and deaths from diphtheria as shown by tables presented.—*Week. Bull.*, New York Dept. of Health, June 28, 1930.

Public Health in Iowa—A study has been made of the public health machinery of Iowa, official and unofficial, and its relationship and coördination with the State Health Department. The present organization and divisional activities of the State Health Department have been studied and recommendations for reorganization enumerated. Iowa spends less per capita each year for public health than any other state in the Union. In 1925 the average per capita expenditure for 48 states was 9 cents. Iowa was at the bottom of the list of the 10 states which appropriate less than 5 cents per capita, the amount for this state being 2.4 cents. It is recommended that as a beginning this be increased to 5 cents.

Instead of building up a large central organization for the supervision of health activities it is recommended that local units of the county type be created and maintained under constant supervision and control of the State Health Department. A full-time county health department will most adequately meet the health needs of each local district.

It is recommended that the State Medical Society recognize and accept the obligation for providing adequate medical advice and treatment for all citizens at a reasonable cost. The Governor should appoint a special public health advisory council for the purpose of coördinating all public health activities in Iowa.—A. J. McLaughlin, A Public-Health Survey of Iowa, *Pub. Health Rep.*, 45, 1573 (July 11), 1930.

Tuberculosis Service in Cattaraugus County—Beginning January 1, 1923, through the coöperation of the Milbank Memorial Fund, the first rural county-wide organization for the control of tuberculosis was established in New York State. In that year a County Board of Health was created with one bureau devoted to tuberculosis control. The county with its 75,000 inhabitants and 1,343 square miles was divided into 6 administrative health districts with case finding, clinic, nursing and medical personnel available for each district.

During the 10 years prior to the beginning of this demonstration, there was reported an average of 1.4 new cases per annual death. In 1924, the first year of the campaign, the cases reported as active, apparently arrested, or arrested, gave a ratio of 6.9, which obviously was a cumulative ratio. For 1927 there were 3.7 new cases reported per annual death.

One of the first undertakings in 1923 was the preparation of a living case file. The list of 237 cases was carefully checked and of this number, 102 cases were cancelled, as the patients had either moved from the county, died, or could not be located. In 1923 there were 135 known cases of tuberculosis. In 1927 there were 636 known cases.

In 1926 particular attention was devoted to the examination of contacts. Thirty-two per cent of all cases diagnosed as tuberculous gave a history of tuberculosis in their immediate family.

During the 5-year period 1923-1927, a total of 7,171 persons was examined especially for tuberculosis, or approximately 10 per cent of the entire population of the county. Home treatment for special types of cases which were not hospitalized was given particular emphasis. It has been found that for adequate diagnostic service there should be available a half-day clinic per month for every 5,000 to 8,000 population. It is too early to evaluate the results statistically.—Stephen A. Douglass, *The Organization of a Rural Tuberculosis Service*, Milbank Memorial Fund, 1930.

Los Angeles County Health Department—Los Angeles County was the first county government in the United States to attempt to bring together under one roof health department, emergency medical and surgical service, clinics for the indigent sick, school health service, social service, and other related work in the community, combining the resources of the county government, the municipality and the school district. The first major unit was established for the San Fernando District in 1926. At present there are 13 districts, each having a complete health department or-

ganization. Each unit consists of the following services: (1) community public health, including communicable disease control, sanitation and preventive medicine; (2) school hygiene and educational work under the direction of local school authorities; (3) service to the indigent sick or dependent poor including emergency hospital and clinic work manned by voluntary physicians serving without pay; (4) coördination of social services, medical as well as county division of welfare work.

For the year 1927 the Los Angeles County Health Department was appraised by representatives of the American Public Health Association and scored 820 points out of a possible 1,000.

Preschool hygiene rated 100 per cent; laboratory work and popular health instruction and prenatal work scored over 90 per cent while sanitation, infant hygiene, vital statistics and tuberculosis were rated each approximately 80 per cent. The weakest divisions of the department were venereal disease and communicable disease control.—J. L. Pomeroy, *Report of Los Angeles County Health Department*, June 30, 1929.

PREPARATION OF ACIDOPHILUS MILK FROM MILK TREATED BY ELECTRICITY*

E. D. DEVEREUX

*Michigan Agricultural Experimental Station, Michigan State College,
East Lansing, Mich.*

REVIEW OF LITERATURE

BEFORE a desirable cultured milk of any type can be prepared it is necessary to reduce the bacterial content of the milk to be inoculated to a negligible quantity. Heat has been the common means and several temperatures and exposure periods are being used.

In the preparation of *Lactobacillus bulgaricus* milk Hammer and Hauser (1916)¹ stated that, if the original milk was very clean, pasteurization at 82° to 93° C. for 30 to 40 minutes might be satisfactory; but if not, double pasteurization was ordinarily effective. This consisted of pasteurizing on two successive days with thorough cooling during the time between heatings. Hammer also suggested that when large lots of the milk were to be prepared double pasteurization was advisable unless the milk was very clean.

For the preparation of *Lactobacillus acidophilus* milk, Prucha and Brannon (1926)² pasteurized skim milk of a good quality at 79° to 80° C. for 30 minutes, cooled to 37° or 38° C., allowed it to stand 3 to 4 hours, and then repasteurized. Kopeloff (1926)³ suggested pasteurizing skim milk at 90° to 93° C. for 1 hour. The milk was then cooled to 37° C. for 3 to 4 hours and repasteurized.

Reichart and Davis (1928)⁴ are of the opinion that the above mentioned

methods are rather tedious and the results somewhat uncertain. They suggest heating the milk under a pressure of 12 to 15 lb. at a temperature of 118° to 121° C. for 30 minutes.

In all of the above mentioned methods for preparing acidophilus milk, a 2 to 3 per cent inoculum of *L. acidophilus* was used, and the milk incubated at 37.5° C. for 18 to 36 hours.

EXPERIMENTAL

During the past year several phases of pasteurization of milk by electricity have been studied, and in connection with these studies a commercial plant using the electrical method was visited frequently. This plant was using the Electropure process⁵ operating at 70° to 71° C. Samples of raw milk were taken and large samples (1 to 2 liters) were taken following treatment. Plate counts were made according to the *Standard Methods of Milk Analysis* (Fifth Edition), 1927 (Table I). Since only a small portion of the treated milk was used for plating, a large quantity was left for experimental purposes; this was inoculated with about 2 to 3 per cent of a 24-hour culture of *L. acidophilus* and incubated at 37.5° C. for approximately 24 hours.

In every case a desirable product resulted. The curd was fine, soft, easily broken, and very little whey expressed.

TABLE I

Sample No.	Raw Milk	Electro- pure Milk	Percentage Reduction
1	130,000	2,500	98.08
2	400,000	2,000	99.50
3	400,000	2,800	99.30
4	450,000	3,000	99.33
5	40,000	7,000	82.50
6	60,000	5,000	91.66
7	375,000	2,000	99.47
8	26,000	4,800	81.54
9	110,000	2,000	98.18
10	150,000	4,000	97.33
Average	214,100	3,510	98.34

The milk had a taste of freshly soured milk and since the heating was not sufficient to caramelize it there was no decided cooked flavor. Microscopic examination revealed that the growth of organisms remaining in the original milk was unimportant.

DISCUSSION

Milk electrically pasteurized, in a manner no different from that employed

for sale as liquid milk, appears to be suitable for the production of acidophilus milk. The bacterial content of the original milk was reduced to a negligible quantity.

This method of preparing cultured milk has several distinct advantages: (1) ease with which the milk can be prepared for inoculation, (2) whole milk can be used, (3) no special sterilizing equipment is necessary, and (4) a product with a fresh sour taste and not a cooked taste or color is produced.

AN IMPROVED DRYING PLATE

M. O. ROBINSON, V. M. D.

Scott-Powell Dairies, Philadelphia, Pa.

DIRECT microscopic examinations of milk samples have become one of the chief control measures in many laboratories during the past few years. It is a worth while system, and has many advantages.

The Scott-Powell laboratories have used this method quite extensively in their daily control work. Several obstacles had to be overcome in adapting this method to our work; namely, the production of a compact portable outfit, which could be used for hours at a time without attention from the operator.

To meet this demand, we have designed an outfit that has been giving us

excellent service for over two years; and at the present time we are using three such outfits in our control work.

The outfit consists of a small metal carrying case, divided into two compartments. One compartment is asbestos lined, and is covered by a tinned copper plate. This plate is automatically kept at a constant temperature by means of an electric light, which is thermostatically controlled. The thermostat is adjustable to any temperature, to suit the individual operator. When not in use, the 18 ft. of extension cord can be readily coiled up within this space.

The other compartment contains

Improved Drying Plate

metal slide racks of a standard size, so that the whole rack may be dipped into standard staining jars; allowing 20 slides to be stained at one time. There is also a place for pipettes, needles, etc.

On the hot plate, there is a special arrangement for holding the standard size card, for guiding the operator. This card is held in place by a spring arrangement, which also holds the slide firmly in place during the operation of making the smear.

Under actual working conditions we find that this piece of equipment has been of great value to us, in that it is compact, sturdy, and accurate in operation; preventing overheated smears, with the resulting loss of time, and possibly lost samples.

This piece of equipment will be put on the market by the Arthur H. Thomas Company of Philadelphia, under the name of "Robinson Warm Plate and Staining Rack."

DETECTION OF INDOL IN BACTERIAL CULTURES

D. C. B. DUFF

Department of Bacteriology, University of British Columbia, Vancouver, B. C.

DURING recent experiments on the production of indol by various bacterial strains, it was found that the sensitivity of the paradimethylaminobenzaldehyde test, for small quantities of culture (5 c.c.), could be considerably increased by dialyzing the culture into an equal volume of isotonic saline, and performing the test upon the dialysate instead of upon the crude culture. This result is peculiar since presumably only up to one-half of the total indol present can be in the dialysate. Nevertheless, an actually deeper color is given by the chloroform extract from the reaction performed on the dialysate than is given by the extract with the undialyzed culture. Blank tests showed that this intensification of extract color was not in any way due to materials in the dialyzing membrane. The clear test solution afforded by dialysis has the further advantage that the chloroform extracts from such a solution are always clear, thus facilitating comparison with standards. When the crude culture is tested, the extract frequently tends toward cloudiness, due to precipitates formed during the reaction.

Table I refers to results obtained from 5 c.c. peptone water cultures of a

non-indol producing organism (*Staph. citreus*) to which known amounts of indol were added just before placing in the icebox. One series of cultures was dialyzed by the method given. The other series was not dialyzed. The chloroform extracts from both series were compared with color standards freshly made from known aqueous solutions.

It is seen that with crude cultures color begins to show at about 12 mmg., whereas with the dialysates amounts as low as 1 mmg. may be detected (i.e., 0.5 mmg. or less in the dialysate). As the amount of indol is increased, the value found for the dialysate tends to approach more closely one-half of the total amount of indol originally present in the culture. A smooth curve could not be drawn of this approach, possibly due in part to the gap of 2 mmg. between standards, and the impossibility of accurately judging values between standards. It should be mentioned that the dialysis method was also attempted with cultures of bacteria grown in macerated salmon flesh. Satisfactory results were not obtained, due to the passage through the cellophane membrane of substances which formed a heavy precipitate in the test. The use, however, of another type

TABLE I

Mmg. Indol in culture		0	0	1	2	4	8	12	16	20	24	30	34	40	44	50	100
Mmg. Recovered in Test	Not Dialyzed	—	—	—	—	—	—	trace	2	5	6	8	8	10	10	14	30
	Dialyzed	—	—	trace	trace	1.5 apx	3	5 apx	6	8	10	12	15 apx	18	20	24	50

of membrane might make it possible to apply this method to testing the production of indol in spoiled fish or meat. At present the most satisfactory method for such determinations is that of steam distillation as described by Clough.

TECHNIC

Cellophane* was the dialyzing membrane used. This material has been described by Hill, and by Wilson, as a sterilizable dialyzing membrane useful in bacteriological procedures. The organism to be tested is inoculated into 5 c.c. quantities of tryptophane broth in 5" x $\frac{1}{2}$ " lipless tubes. After 48 hours' incubation, the cotton plugs are removed and an unpunctured sheet of cellophane, about 6" x 6", is folded down tightly over the mouth of each tube by means of several turns of a rubber band. The cellophane tube or bag thus formed is then slid part way off the test tube, still remaining bound to it by the rubber band. The test tube is now inverted, allowing the culture fluid to fall into the dialyzing bag. The inverted test tube with its dependent bag is then hung within an 8" x 1" tube containing 5 c.c. of a saline solution isotonic with the medium. The unit is placed in the icebox for 24 hours. The bags are removed, and any fluid adhering to the outer surface is washed down into the dialysate with a few drops from a washbottle. The clear dialysate is then pipetted off into a 6" x $\frac{5}{8}$ " tube, in which it is subjected to the test. Comparison

with color standards is facilitated if the chloroform extract is pipetted off into a still smaller clear glass tube which is placed in a comparator with the standards.

Icebox dialysis is particularly necessary in the case of cultures of motile organisms, which may at higher temperatures penetrate the membrane in such numbers as to cloud the reaction. Formalin as an immobilizing agent is useless, since even in very low concentrations it has the effect of almost completely inhibiting the reaction. Other antiseptics were not tried.

Clough has given a comprehensive review of the various tests for indol and skatol. He recommends a modification of the Ehrlich test. This has given complete satisfaction in this laboratory, and for convenience is reproduced below.

Reagents:

- (a) Paradimethylaminobenzaldehyde, 2 gm. in 100 c.c. of 95 per cent alcohol.
- (b) HCl, 600 c.c. concentrated plus 200 c.c. water.
- (c) Chloroform, U. S. P.

Method:

To 5 c.c. of the test solution add 0.5 c.c. reagent (a) and 1 c.c. reagent (b). Place in boiling water bath for 20 seconds, shaking vigorously, then place in ice water $\frac{1}{2}$ minute, and extract with 1 c.c. reagent (c). Comparison is made with standards made in the same way.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Post-Sanatorium Histories of Tuberculous Cases—The present study is a report of after-histories of 7,000 patients discharged from two state sanatoriums. The largest group of men in both institutions were skilled workers and the largest group of women, housekeepers. The age at admission ranged from 10 to 60 years.

At the end of the 5th year after discharge, there were complete records for 190 minimal, 318 moderately advanced, and 57 far-advanced cases. Seventy-two per cent of the patients in the minimal stage worked the entire 5 years and 8 per cent worked continuously after the first year. The moderately advanced cases reported 69 per cent working for the 5 years and 8 per cent working after the first year. The far-advanced cases showed 46 per cent working the entire period and 2 per cent after the first year. Only 7 per cent of the far-advanced cases did not work at any time during the 5 years.

After 10 years, there were living 31 minimal, 63 moderately advanced and 10 far-advanced cases. Of these, 58 per cent of minimal, 68 per cent of moderately advanced, and 33 per cent of far-advanced worked the entire period.

Fifteen years after discharge, 62 per cent of the minimal cases were living, and 82 per cent of these were known to be working. Of the moderately advanced cases, only 30 per cent were living in the 15th year and 78 per cent of these were known to be working. The far-advanced cases died very rapidly; in the 15th year only 8 per cent were alive.

Women who entered sanatoriums between 20 and 29 years of age in the minimal stage showed the best survival

rates. In both the minimal and moderately advanced stages, women under 20 died more rapidly than men of the same age. For women already far-advanced when entering, the ages 30 to 39 seemed most favorable. Age was a more direct factor with men. Males in the moderately advanced stage had less chance of living if in the age group 20 to 29 than if under 20 or between 30 and 39 years of age.

The length of sanatorium treatment directly affected far-advanced cases and moderately advanced for the first few years after leaving the sanatorium but the effect on minimal cases was not so direct. Weight was shown to be a positive factor in the history of tuberculous patients after leaving the sanatorium, those gaining most while in the sanatorium having the best chance of living for a long period. No definite relationship was shown between nativity and length of life in tuberculous patients.—J. S. Whitney and B. A. Myers, *Am. Rev. Tuberc.*, 691: 701 (May), 1930.

Marriage and Divorce Reports: 1929—

Arizona—During 1929, there were 7,405 marriages performed in Arizona as compared with 6,400 in 1928, representing an increase of 1,005 or 15.7 per cent. The increase is attributed to the fact that the marriage laws in California now require 3 days notice to be given before issuing a marriage license and many residents in California go to adjacent counties in Arizona to be married. This was noticeable in Yuma County where there were 274 marriages in 1926 and 2,190 in 1929.

There were 1,085 divorces granted in

Arizona in 1929 against 1,062 in 1928, an increase of 2.2 per cent. There were 24 marriages annulled in 1929 compared with 19 in the preceding year.

Minnesota—Minnesota has reported 24,109 marriages for 1929 compared with 23,249 performed in 1928, an increase of 860 or 3.7 per cent. There were 8.7 marriages per 1,000 population in 1929 against 8.5 in 1928. There were 2,861 divorces granted in 1929, representing an increase of 0.6 per cent over the preceding year. The number of divorces per 1,000 population was 1.037 in 1929 as against 1.045 in 1928.

Washington—The number of marriages for 1929 in Washington increased 4.5 per cent over 1928; there were 19,685 marriages performed in 1929 and 18,833 in 1928. Divorces, however, showed a decrease of 1.5 per cent from 4,554 in 1928 to 4,486 in 1929. Annulments increased from 58 in 1928 to 64 in 1929. The number of marriages per 1,000 population was 12.2 in 1929 against 11.9 in 1928, and the number of divorces was 2.78 per 1,000 population in 1929 against 2.87 in 1928.

Utah—The number of marriages in Utah in 1929 was 11.6 per 1,000 population compared with 11.0 in 1928. The actual number of marriages performed was 6,286 in 1929, representing an increase of 7.6 per cent over 1928. There were 1.88 divorces per 1,000 population in 1929 against 1.92 in 1928. The number of divorces was 1,016 in 1929, a decrease of 6 or 0.6 per cent since 1928.

Vermont—The Department of Commerce has announced that there were 2,712 marriages performed in Vermont during 1929 as compared with 2,997 in 1928, a decrease of 9.5 per cent. The marriage rate per 1,000 population was 7.7 in 1929 against 8.5 in 1928. There were 406 divorces granted in the state in 1929, an increase of 2.5 per cent over 1928. The divorce rate per 1,000 population was 1.15 in 1929 and 1.12 in 1928.

Connecticut—Connecticut reported an increase of 5.6 per cent in marriages in 1929 over 1928, the number performed being respectively 12,303 and 11,650. There were 1,221 divorces granted in 1929 as compared with 1,276 in 1928, a decrease of 4.3 per cent. The marriage rate for 1929, 7.2 per 1,000 population, was higher than that for 1928, 7.0; the divorce rate fell from 0.77 per 1,000 population in 1928 to 0.72 in 1929.—

U. S. Bureau of Census, *Preliminary Reports on Marriage and Divorce: 1929*.

German Cancer Statistics—During the period 1923–1927, 185,600 persons died of cancer in Prussia; of these 81,200 were men and 104,400 were women. The digestive organs were involved in 129,500 persons; reproductive in 26,700; respiratory, 5,700; urinary organs, 3,975; and in only 1,990 the external covering of the body. About 2 per cent of the cases were in organs of sense, the nerves, bones and joints. No reference to site of cancer was given in from 4 to 5 per cent of cases. Involvement of digestive organs was about 6 per cent lower in females than in males; cancer of respiratory organs was a little lower in females than males and cancer of the urinary organs was only a trifle more than two-fifths of that of the male sex. In cancer of the reproductive organs, women presented about 15 times as many fatal cases as men.—*Med. Off.*, 43: 285 (June 21), 1930.

Population Decreases in German Cities—From 1900 to 1927, there was a rapid decrease in the excess of births over deaths in all the large German cities. Berlin had an excess of deaths over births; in 1900, Berlin's excess of births over deaths was 7.7 per cent and in 1927 the excess of deaths over births amounted to 1.4 per cent. In Munich, the capital of Bavaria, the excess of

births over deaths in 1900 was 10.6 per cent; then there was a downward trend, until in 1927 the low point of 0.9 per cent was reached. Only slightly better were the reports from Dresden with 1.2 per cent, Hamburg with 1.4 per cent, Frankfort-on-Main and Magdeburg with 1.6 per cent, Altona with 1.7 per cent and Leipsig with 2.0 per cent. In the remaining large German cities, the figures were somewhat higher but in few was the excess of births over deaths above 10 per cent, whereas in 1900 the percentages ranged from 15 to 20, and in one case, 34 per cent.—*J. A. M. A.*, 94: 1856 (June 7), 1930.

Body Weight and Certain Causes of Death—High death rates from the degenerative diseases among overweights cause a marked reduction in their life expectation. Persons who are underweight, on the other hand, have high death rates from the respiratory diseases, but this unfavorable feature is usually balanced by their low death rates from the degenerative diseases. Although these general observations were made many years ago, there has been little extensive information regarding the mortality from the important causes of death in various weight groups. Fortunately, records of the Union Central Life Insurance Company, made available to the Statistical Bureau of the Metropolitan Life Insurance Company some years ago, have made possible an analysis of this kind. The following represents a summary of the more important results of the investigation recently published in *Human Biology*, May, 1930.

Taking the death rate of the normal weight group as 100 per cent, it was found that overweights, as a whole, had a mortality from heart disease 151 per cent of the average. Similarly, the death rate of overweights from nephritis was 172 per cent of the normal; from arterial diseases, 165 per cent; from

cerebral hemorrhage, 157 per cent; and from cancer, 111 per cent. There were appreciable excesses in the death rates among overweights from angina pectoris, influenza, paralysis, appendicitis, cirrhosis of the liver and typhoid fever. The accident and suicide death rates among overweights were also higher than the average. Underweights, on the other hand, show generally lower death rates from the above causes. The mortality from heart disease was only 81 per cent of the average; from nephritis, 77 per cent; from arterial diseases, 74 per cent; from cerebral hemorrhage, 70 per cent; and from diabetes, only 64 per cent. The mortality from cancer among underweights, as a class, was approximately the same as among normals.

Of the diseases which showed high death rates among underweights, tuberculosis stood first by a wide margin. As a group, their mortality from this cause was 202 per cent of the normal, but among those 15 per cent or more underweight it was 291 per cent. The death rate from pneumonia was also high among underweights. As a class, their mortality from this disease was 111 per cent of the normal, but it was even higher among those who were extremely underweight. No other important disease caused a relatively high death rate among underweights.

It would seem that the high death rates among overweights from the degenerative diseases is largely due to the burden of work put on the heart, kidneys and blood vessels by the extra body bulk. Overweight is often due to the dietary habits and the mode of life of the individual and such overweight can be modified with great benefit to health and longevity. Taken altogether, underweight, biologically, seems to be an asset. It represents the most efficient type in respect to metabolism.

The present study, then, confirms the previous observation that persons who approach the mean of build or weight

are best suited to withstand the hazards of life. The greatest problem today in the field of public health is to keep down the mortality in middle and later life, and it is not unlikely that public appreciation of these facts regarding body weight may help in its solution.—*Stat. Bull., Met. Life Ins. Co.*, 11: 4-6 (June), 1930.

The Causes of Neonatal Deaths—A study of 800 cases of death within the first 28 days after birth has been made in Glasgow. In this series 71 per cent of the infants died within 7 days. Of the remainder, 18 per cent died during the second week, 8 per cent during the third week, and 3 per cent during the fourth week.

The two main groups of causes of death among new-born infants are injuries or disturbances due to delivery and illness or infection. In this series there were 540 cases of asphyxia neonatorum in the first group, 140 mature and 400 premature. In 51 of them, some pneumonic consolidation was found. Many of these showed birth injuries; 146 had gross intracranial hemorrhage, and 121 had tears in the dura. Sixteen of this group showed mental anomalies and 15 of them had syphilitic mothers.

Generalized septicemia was found in 120 infants, often in association with pneumonia. Pneumonia was the most common lesion, appearing in 197 cases,

and in practically two-thirds of all non-asphyxial or atelectatic cases. Infections of the gastrointestinal tract were rare in this series even after a history of diarrhea and vomiting. One premature infant had appendicitis associated with generalized septicemia. Peritonitis was present in 21 mature and 23 immature babies. One child had jaundice due to obstruction by a congenital band and two had splenomegaly.

There was gross intracranial hemorrhage in 161 cases, 86 per cent of whom died within the first week and 36 per cent during the first day. Twenty cases showed some form of infection while the remainder died from asphyxia and atelectasis. Meningitis occurred in 33 cases, most of the infants dying between the 5th and 13th day. It was associated with septicemia in 29 cases and with pneumonia in 12 cases. There were 17 examples of abnormality of the central nervous system.

Cellulitis was found in 19 mature and 10 premature infants and swabs revealed streptococci in 10 cases, staphylococci in 7 and coliform bacilli in 3 cases. The 6 cases of pemphigus included were part of an epidemic of 15 cases of whom 7 died from general sepsis. There were 30 cases of thrombosis; in 11 of these the mother had some form of toxemia. The Wassermann reaction was positive in 26 cases. Congenital syphilis is not a common cause of neonatal deaths.—*Lancet*, 1: 1032-1034 (May 10), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

SANITATION OF "PULLMAN CITIES" AT SHRINE CONVENTION

Toronto, June 9-12, 1930

J. ROSS MENZIES

*District Engineer, Department of Pensions and National Health,
Montreal, Canada*

WHEN it became definitely known that the 1930 Convention of the Masonic Shrine would take the form of an International Peace Celebration at Toronto, Canada, the various official bodies concerned took measures to maintain a high standard of sanitation at the temporary living quarters provided by the Pullman cars to prevent outbreaks of communicable diseases. When consideration is given to the possibilities of such outbreaks, where representatives are gathered from all parts of Canada, the United States and adjacent countries, the necessity for such action is readily apparent.

Experience with a similar convention at Miami, Fla., and all other information and data on this particular phase of sanitation were reviewed. There then were held two meetings, one in April and the other in May, to consider in detail the sanitation of steamships in local waters and the sanitation of the two concentrated areas wherein the Canadian National and Canadian Pacific Railways proposed to establish two Pullman cities.

The groups coöperating in these meetings included the Department of Health, Toronto; the National Department of Health of Canada; the Commission of Parks, Toronto; the Departments of

Works and of Street Cleaning, Toronto; two Shrine committees, and the two railroads involved. The representatives of these groups worked out the general plan of procedure which is explained here in more detail.

Steamships to be used in lieu of hotel accommodations were required to obtain their drinking and culinary water from safe shore sources. Such vessels had to be equipped with retention tanks for raw sewage, which was not allowed to be dumped within ten miles of any water works intake, and then only after having been boiled for 30 minutes. The application of the regulations regarding vessel sewage disposal was obtained with the coöperation of the U. S. Public Health Service.

Representatives of the railways agreed to make adequate provision of men and materials so that difficulties experienced at Miami would not be repeated. Precautions included screening of sewage, protected covering between toilet outlet and sanitary can, and provision for disinfection of sanitary equipment and grounds around disposal sheds and cars. The Toronto Department of Street Cleaning arranged for continuous removal of garbage from the coach yards.

Both the Canadian National and the Canadian Pacific Railways erected

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

SANITATION OF "PULLMAN CITIES" AT SHRINE CONVENTION

Toronto, June 9-12, 1930

J. ROSS MENZIES

*District Engineer, Department of Pensions and National Health,
Montreal, Canada*

WHEN it became definitely known that the 1930 Convention of the Masonic Shrine would take the form of an International Peace Celebration at Toronto, Canada, the various official bodies concerned took measures to maintain a high standard of sanitation at the temporary living quarters provided by the Pullman cars to prevent outbreaks of communicable diseases. When consideration is given to the possibilities of such outbreaks, where representatives are gathered from all parts of Canada, the United States and adjacent countries, the necessity for such action is readily apparent.

Experience with a similar convention at Miami, Fla., and all other information and data on this particular phase of sanitation were reviewed. There then were held two meetings, one in April and the other in May, to consider in detail the sanitation of steamships in local waters and the sanitation of the two concentrated areas wherein the Canadian National and Canadian Pacific Railways proposed to establish two Pullman cities.

The groups coöperating in these meetings included the Department of Health, Toronto; the National Department of Health of Canada; the Commission of Parks, Toronto; the Departments of

Works and of Street Cleaning, Toronto; two Shrine committees, and the two railroads involved. The representatives of these groups worked out the general plan of procedure which is explained here in more detail.

Steamships to be used in lieu of hotel accommodations were required to obtain their drinking and culinary water from safe shore sources. Such vessels had to be equipped with retention tanks for raw sewage, which was not allowed to be dumped within ten miles of any water works intake, and then only after having been boiled for 30 minutes. The application of the regulations regarding vessel sewage disposal was obtained with the coöperation of the U. S. Public Health Service.

Representatives of the railways agreed to make adequate provision of men and materials so that difficulties experienced at Miami would not be repeated. Precautions included screening of sewage, protected covering between toilet outlet and sanitary can, and provision for disinfection of sanitary equipment and grounds around disposal sheds and cars. The Toronto Department of Street Cleaning arranged for continuous removal of garbage from the coach yards.

Both the Canadian National and the Canadian Pacific Railways erected

galvanized iron construction and was located at the north side of the yard over a city sanitary sewer. Two hoppers were provided into which the cans were emptied. These hoppers had special flared tops to prevent back splashing. Water jets played over the interior continuously and another jet discharging upward in the hopper and controlled by a foot valve was used in washing out the cans as soon as they were emptied. The cans were then sprayed with a disinfectant by means of a compressed air gun and were then ready for use once more. A special screen was provided, about $2\frac{1}{2}'$ below the hopper mouth, to intercept bottles and other large articles which would be liable to clog the sewer. A 2" pipe connection was also made to the sewer and liberal quantities of water were discharged into it from time to time to assist in washing away solid material. Disinfectant was sprayed freely around the disposal shed and on the trucks used for transporting cans. To assist in the absorption of waste water and spillage from sanitary cans, about 3" of gravel and sand were placed between the rails and the concrete walks and this was raked or turned over as occasion demanded.

Watering cans were provided for spraying the ground around coaches but it was not found necessary to use much disinfectant in this way.

Special temporary buildings were provided for shower baths. These were of frame and galvanized iron construction. Water was heated in a large tank connected to the yard steam lines, and the hot water was kept in constant circulation by a centrifugal pump. In the women's section, the showers were divided into two parts by waterproof curtains, the outer compartment being supplied with a bench and used as a dressing room. Mirrors were hung in the aisle and attendants distributed soap and towels. In the men's section, there was only one compartment to a shower

and benches were provided in the aisle. The spraying device was connected to the hot and cold water pipes by a rubber hose. The hose used originally was found to be too light, and some trouble occurred because it became disconnected. This difficulty was overcome by using heavier hose. A charge of \$.25 was made for a shower.

Garbage was collected in covered metal cans and transported on trucks to an enclosed yard where it was sorted and dumped into city wagons. These were removed to the city incinerator by the city street cleaning department on a schedule of continuous service.

Toilet and rest rooms were located in the administration building at the eastern end of the yard; fire hydrants were provided throughout the yard and chemical extinguishers were also available. In addition, city fire alarms were placed in the yard. Barber shop, beauty parlor, lunch counter, information bureau and taxi service were all available within the yard. Electric light standards supporting two lights with reflectors were located at regular intervals along the concrete walks and provided ample light.

At the "Temple Park Annex" coach yard of the Canadian National Railway, everything was handled in the same way as in the main yard with minor exceptions.

Showers, toilets, wash rooms and an information bureau were to be found in a building at the south side of the yard. A disposal shed similar to that in the main yard, but with only one hopper, was placed at the east end of this building, and a latrine for the use of employees was located at one end of the disposal shed. This was supplied with sanitary cans which were removed from time to time, through a flap door, by the disposal shed attendant to be duly emptied and disinfected.

The walks in this yard were of plank and were located between alternate rows

of cars. Between rows not occupied by walks a narrow gauge track was laid, with turntables at convenient points, and small trucks, pushed by hand, were used in transporting ice and sanitary cans. Water hydrants were located on temporary pipe lines laid on the surface of the ground and were nearly at ground level. They were equipped with steam hose couplings for the ready attachment of service hose.

Considerable ingenuity was displayed in this yard in connecting sanitary cans to toilets. Stove pipe elbows were found very useful in some cases.

Ninety-seven coaches were located in this yard and 45 men were employed to care for them. Seven men supplied water, 8 supplied ice, 19 acted as sanitary men, and 11 were engaged in cleaning the yard. There were 36 shower baths, 24 being for men and the remainder for women. Five fire hydrants were located in the yard and a 25-gallon chemical fire extinguisher was also available in addition to small ones in the coaches.

There were 3,000 sanitary cans provided to supply the two Canadian National Railway yards and 2,400 pipe connections for these cans were also available.

TEMPLE PARK AND TEMPLE PARK ANNEX ARRANGEMENTS

Equipment for supplying water and ice was apparently quite adequate with the exception of rubber gloves for the men and metal protectors for the water hose when not in use.

The supply of sanitary cans was ample but during the early stages of the convention some difficulty was encountered in making satisfactory connections between the cans and toilet outlets. This was due to many of the outlets leaving the cars on a slope. By using tinsmith's snips and, in some cases, pipe elbows, this difficulty could usually be overcome. In a few cases where toilets discharged directly over wheels and

trucks, it was quite impossible to provide satisfactory means of collection. Constant supervision was necessary to discover toilets which had not been supplied with cans. In many cases the outlets were very difficult to locate, but,

*Sanitary Can in Position, "Fez City"
(C. P. R.)*

after once being used, it was easy to find them and provide cans.

Owing to the heavy discharge of liquids from dining cars these were a continual source of trouble, and larger collection vessels were found very useful. A plentiful supply of dry sand and gravel was also of considerable assistance.

Disinfectant was used freely around the disposal shed, on the trucks, and in a few cases around the coaches. At no time during the convention was any objectionable odor noticeable in the yards, nor were any flies seen.

On June 10, a heavy rain caused some difficulty due to the increased use of toilet facilities and unpleasant working conditions. During the remainder of

Sewage and Garbage Disposal Yard, "Fez City" (C. P. R.)

the convention the weather was fair and moderately cool and no trouble was encountered in keeping everything in a satisfactory condition.

As soon as the coaches were removed, the yard was cleared of rubbish, garbage, and cans, and the tracks were sprayed with disinfectant.

**"FEZ CITY" COACH YARD, CANADIAN
PACIFIC RAILWAY**

This yard, located at the south end of Bathurst Street, was constructed expressly for the parking of coaches used as living quarters during the convention, and is to be torn up when no longer needed.

Another View of Sewage Disposal Yard "Fez City" (C. P. R.)

Hydrants, connected to the city water supply, were located at regular intervals throughout the yard, and steam hose couplings were used on the hydrants and filling hose for ease in coupling them. The filling end of the hose was not provided with any attachment, nor was it protected in any way when not in use.

Ice was stored at the side of the yard in a refrigerator car and, when required for use, was transported to the cars in metal wheelbarrows painted white. Galvanized pails were used to carry broken ice into the cars. The service men were supplied with white uniforms and white rubber gloves.

Garbage and rubbish were collected in open end carbide cans from the yard. From time to time these containers were taken to the disposal yard and emptied into city garbage wagons to be disposed of at the city incinerator.

A special corrugated sheet metal building was constructed and equipped with two compartment showers. The outer compartment was arranged for a dressing room and contained a chair. The walls and doors of the showers were also of sheet metal. Attendants supplied towels and soap, a charge of \$.50 being made for the accommodation provided. Toilets, latrines, wash basins, and a barber shop were also located in this building. The section reserved for women was equipped with toilets, wash basins, showers and a sitting room.

To provide toilet and bath facilities for porters employed on the cars, an old box car was removed from its trucks, reconditioned and fitted with similar conveniences, the effluent from the baths and toilets being discharged into a city sewer.

Sewage disposal cans, 11" in diameter and about 35" long, were specially constructed for the collection of sewage from the cars. A 6" ring of galvanized metal, the same as used in the cans, fitted into the top of the cans, and a heavily oiled cloth was fastened to the

inside of this ring. This cloth was wired around the toilet and waste pipe outlets when the can was in place. Handles were also fitted to the cans for ease in handling. On the side of the tracks where no walks were provided, 10" planks were nailed to the ties and provided a level base for the cans. Close fitting metal covers were placed on the cans when transporting them to and from the disposal yards on trucks hauled by a small motor. The contents of the cans were emptied into 50-gal. wooden barrels provided with covers which could be clamped tightly in place. These barrels were then removed by truck and emptied into a city sanitary sewer. The sanitary cans were washed out with water and this water was dumped into a septic tank which overflowed into a city storm sewer. After washing, the cans were disinfected, the covers replaced, and they were ready for use again.

Between alternate rows of coaches, walks were built up of clay and finely crushed rock, enough of the latter being included to provide good drainage. Electric lights were strung on wires supported by wooden poles located in these walks. Two stationary locomotives furnished steam for the coaches and hot water for the showers.

At the entrance to the "city," two large tents were located, one being used as a lunch counter, and the other as an information bureau, telegraph office, and express office. A frame administration building was located on an elevation at the western end of the yard.

There were 328 coaches, including dining cars, located in this yard, requiring extra men.

COMMENTS ON "FEZ CITY"

The type of cans used in this yard seemed to be more easily attached to the toilet outlets than were those used by the Canadian National Railways. This was particularly true in the case of sloping outlets, the advantage being the

larger opening provided. In some cases, where outlets extended considerably below the coaches, shorter cans were necessary. The same difficulty with regard to toilets not being provided with cans was encountered in this yard

as in the Canadian National Railways and constant supervision was necessary to locate and remedy the oversight.

No undesirable odors were noticed throughout the yards at any time, and very few flies were seen.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Occupational Skin Diseases from the Biological Point of View—The author has devised a set of routine eczema tests of a number of substances known to cause eczema and has applied them to working men in various trades with very practical results. These conditions are either due to congenital sensitivity or, as is most frequently the case, a sensitivity developed through previous contact. Such contact may not necessarily be directed to the skin but may come from absorption from another place as from the mouth or the gastrointestinal tract, or by intravenous injections. The process is essentially an allergic one, but does not seem to lend itself to the demonstration of specific antibodies.

The author's investigations have suggested the best prophylactic procedure of occupational eczema to consist in routine testing with the various eczema tests, choosing especially the substances with which the worker may come in contact. Any new employee who gives clearly positive reactions should not be employed where the given industrial exposure may occur. Where the harmful substances are known in the industries an attempt should be made to replace them. In the end, only those workers whose skins show a negative reaction to the given eczema tests should be allowed to come in contact with them.

In a practical way, the method used

in a machine shop showed that a certain rust protector was the cause of eczema and with its elimination the eczema ceased.

Where the eczema is caused by a sensitization it should be possible to desensitize the patient and thus avoid a relapse. This was successfully done in the case of eczema due to oatmeal. However, much more work has to be done along this line. There is hardly a manufactured product which cannot cause an eczema, and these are becoming more numerous in our increase of industrialization.—Prof. Bruno Bloch (Zürich), *J. State Med.*, 38, 7: 373–382 (July), 1930.

What Protects the Skin Against Light?—The author concludes, as a result of many experiments, that it is the thickness of the horny layers of the epidermis which protects against the effects of ultra-violet light rather than the deposition of pigment which occurs in the deeper layers of the epidermis (stratum Malpighi). Thus, the negro may not be much more protected than the white, at least until a thickening of the horny layer has occurred.

The conjunctiva of the eye is known to be very sensitive to light rays, and it was found in the case of a white rabbit to be 200 times more sensitive than that of its non-pigmented skin.

The marked light protection of the

horny layer depends somewhat upon the dissemination of light through a cloudy medium, but principally upon absorption. The absorption substances which, as building blocks of keratin present, are aromatic aminoacids such as phenylalanine and tyrosin. These absorb the erythema-productive ultra-violet rays just as strongly as quinine. Likewise cystin plays a not unimportant rôle in light absorption.

The function of pigmentation, which occurs in the deeper layers of the epidermis, which is also an excellent ultra-violet filter, is to act as a protector to the underlying connective tissue. Thus, after the raying of a spotted pigment area of skin one finds that under the pigmented spots the connective tissue is quite intact, while under the non-pigmented epidermis there is a great degree of destruction. "The pigment layer is therefore the sunshade for the cutis, just as the horny layer is the sunshade for the epidermis." It is very probable, also, that the pigment absorbs heat rays, thus protecting the body from an undue amount of warmth entering from without, although this still needs exact investigations and confirmation. — G. Miescher, M.D. (Zürich), *J. State Med.*, 38, 7: 387-391 (July), 1930.

Natural Gas—The gas bearing sands, so far as is known, have probably always stored natural gas. In 1821, the first gas well in the United States was drilled in Fredonia, N. Y., and three years later, residents were able to use it for illuminating purposes. The first gas well in Pennsylvania was drilled inadvertently in 1840, when salt water was being sought. The boundaries of the great modern fields are in Louisiana, Texas, California, and Oklahoma. Piping to outlying territories began in Pennsylvania about 1880. Now pipelines lead to Northern Alberta, Atlanta, Denver, while two lines are now proposed for Chicago. The dream is that a net-

work of piping will eventually lead natural gas to all populous centers. An important by-product is gasoline.

Something of the growth of the industry can be seen in the statement that in 1906, 885,000 consumers used natural gas; in 1928, the number had increased to 4,366,000, with the prospect of an early addition of more than a million new users through pipelines then under construction.

(There are next discussed the qualities or composition of natural gas, its production, the gasoline plant, carbon black plants, pipeline construction and maintenance.)

In the classification of jobs, all employees are males, and the chief hazards are named. The article ends with a 2-page discussion of potential health-hazards by Carey P. McCord.—*Industry Report*, Retail Credit Company, Atlanta, Ga., V, 6: 67-76 (June), 1930.

Studies in Natural Illumination in Schoolrooms—This is Part III of these studies and concerns the effect of clouds on daylight illumination and on daylight ratios. Parts I and II are contained in *Public Health Bulletin*, No. 159.

While many of the ratios and standards determined vary according to the season, the hour of the day, and the extent of cloudiness, a number of important conclusions, some of which we have already agreed to from practical experience, but some quite new ones, are derived from the study made. (Illustrations, tables, charts and appendices accompany.)—A. F. Beal, Physicist. *Pub. Health Bull.*, No. 188, 128 pp., 1929, price 25c. (Supt. of Documents).

Heating and Ventilating in Schools and Factories—The Industrial Health Research Board has published the results of a study by Dr. H. M. Vernon and Mr. T. Bedford. The object was to determine how far panel heating and underfloor heating could be

recommended in factories. It was found that panel heating was highly suitable for factories because it maintained an almost uniform temperature at all levels, but data were lacking as to its physiological effects.

Underfloor heating, adopted in a few schools, seems likely to increase the comfort and efficiency of workers by raising the temperature at foot level instead of at head level. A series of experiments showed that the temperature of schools must not be less than 55° F. for efficiency in manual work such as drawing and writing. A system of underfloor heating was considered the best for such schools, the panel system for other schools. Both methods distribute heat more evenly than hot water pipes or radiators. There is evidence that in workrooms where most of the floor is exposed and the machinery is light, underfloor heating would be suitable, especially in drafty rooms with big doors that often open to the air.—*J. A. M. A.* (London Correspondent), 94, 21: 1712 (May 24), 1930.

Occupational Cancers—Cancer caused by coal tar and coal tar products with the chemical characteristics of the various coal tars found in the United States, tar distillation and uses of tar and tar products are summarized. The occurrences of skin cancer among tar and pitch workers are summarized in previous studies.

The present investigation has included reports from several large American cities and in particular the analysis of 19 cases of cancer caused by tar, treated in the Memorial Hospital, New York, and in the New York Skin and Cancer Clinic. Another analysis has included Cleveland, where 21 cases have occurred chiefly in a dry-battery manufactory. A summary of statistical results and conclusions is to the effect that the arms and hands are the parts most affected, with the head next, and

the scrotum least. Cancers were caused in 54 per cent by pitch, in 35.1 per cent by tar, and in 5.4 per cent by tar oil. Gas works' tar and pitch were responsible for 70.2 per cent of the cases, while only 5.4 per cent were due to coke oven tar and pitch; hence the latter is proved much less injurious than the former. It is thought that the presence of olefins in gas works' tar is the cause of cancer. The likelihood of cancer is greatly influenced by the slighter susceptibility to skin cancers on the part of negro workers.

The occurrence of skin cancer among oil workers was likewise studied and a review of 21 cases caused by mineral oils is given in the present investigation. Mule spinners' cancer (cancer of the scrotum) has been all but absent among the cotton textile mill-workers of the United States, in contrast to those of Great Britain. The author argues that the mechanical irritation theory of Robertson is therefore negated since the same types of clothing and other physical conditions are the same in both countries. Hence, the difference must be chemical in nature. As an explanation, it is suggested that the effect of sulphuric acid used in the processing of American mineral oils has a destructive effect on the cancer producing substances of the oil. This strong acid treatment removes olefins and other unsaturated hydrocarbons very effectively. (Tables and bibliographies accompany.)—Imre Heller, *J. Indust. Hyg.*, XII, 5: 169–197 (May), 1930.

Poison Alcohol—In response to a request from Rep. Grant M. Hudson of Michigan to Surgeon General H. S. Cumming for information regarding the toxic properties of wood alcohol and methanol, the Surgeon General submitted memoranda from Carl Voegtlin, Professor of Pharmacology, Hygienic Laboratory, and a statement by Reid Hunt, Harvard Medical School, the latter re-

printed from *Industrial and Engineering Chemistry*, 17, 7: 763 (July), 1925.

Professor Voegtlin replied, in part, as follows:

It has been well established that synthetic methanol has the same type of toxic action as ordinary wood alcohol. The earlier claims that synthetic methanol is less toxic than wood alcohol have been proved to be false. It is true, however, that certain samples of crude wood alcohol may contain some allyl alcohol, which is more toxic than methanol. Methanol is readily absorbed by the animal system when given by mouth. The poison is also taken up through the lungs when animals or man are exposed to methanol vapor in air. Thus it has been shown by experiments on rats and dogs that the total amount of methanol absorbed through the respiratory tract varied from 0.32 to 0.55 gram per kilogram of body weight. Methanol is slightly more volatile than ethyl alcohol and grain alcohol, and there are several records in medical literature reporting methanol poisoning in painters using paints containing methanol. The danger of poisoning would be especially great when the painters work in poorly ventilated or closed rooms.

There are also records in the scientific literature indicating that the repeated administration of methanol or methanol-containing preparations to the human skin may cause methanol poisoning and blindness.

To sum up, it would seem that the indiscriminate substitution of synthetic methanol for ethyl alcohol in the manufacture of paints, varnishes, antifreeze solutions, cosmetics, etc., would involve a serious hazard to the health of people. Certain states in the Union have enacted laws prohibiting the use of methanol in all preparations intended for internal administration.—

Congressional Record, 71st Congress, Second Session, House of Representatives, Thursday, June 5, 1930.

Epidemic of Dermatitis Venenata Due to a Hitherto Undescribed Cause—A very acute watery eruption involving hands and wrists and other parts which may have come in contact with the blood and tissues of certain rabbits, while skinning and dressing them, has been produced in a number of instances in North Carolina. The affliction usually lasts about a week and strongly resembles that due to poison

sumach, but is apparently an entirely new affliction.—*F. R. Taylor, J. A. M. A.*, 94, 24: 1916–1917 (June 14), 1930.

Industrial Medicine—It is pointed out that once the needs have been recognized the peculiar and extensive qualifications necessary to become an industrial physician will be readily solved in the matter of preparation and training. Nowhere, at present, can persons combining all of the qualifications be found, so that it is necessary to take likely candidates and to develop these qualities by a suitable course of training (the various qualities are enumerated).—*J. A. M. A. (Belgium Correspondent)*, 94, 24: 1934 (June 14), 1930.

A German Film on Atmospheric Hygiene—A film, prepared with the cooperation of experts, among whom was Professor Koelsch of Munich, consists of four parts dealing respectively with atmospheric pollutions, injuries to health caused by dust, the history of the campaign against dust, and the gravimetric and optical processes of the quantitative analysis of dust. The producers have announced that a second film on the same subject is at present in preparation.—*Ind. & Labour Inf.*, Internat'l Labor Office, XXXIII, 12: 426 (Mar. 24), 1930.

Compensation Act to be Extended to Asbestosis—While the fibrosis associated with silicosis is in more or less isolated nodules, asbestos fibrosis is a fine cobweb ultimately permeating the greater portion of the lungs and leaving little sound tissue. A special scheme of medical inspection by experts will be set up to cover this feature. The disease hardly becomes definite before 5 years' work in the industry, and if it is detected early and the man removed from it, compensation will not be necessary.—*London Letter, J. A. M. A.*, 94, 26: 2078 (June 28), 1930.

Industrial Diseases and Compensation—This paper by Dr. May R. Mayers of the New York Department of Labor is too comprehensive for abstracting with justice in the space available and yet it contains so much of value that those who are interested should read it in its entirety.

The discussion upon this paper occupies 18 printed pages of the *Bulletin* and involves the number of occupational diseases reported and features of associated interest as the representative of each state and province was called upon (a number of tables are included representing such reports).

Of particular interest are the discussions regarding the costs of compensating all occupational diseases, from which it is deduced by Mr. Wilcox, Chairman of the Wisconsin Industrial Commission, based on their experience there for some years, that the costs are not over 2 per cent and, in fact, are more nearly 1 per cent of the total costs for all expenditures for accidents. A strong plea was also made by some of the discussants for complete coverage compensation laws for occupational diseases, and the doing away with schedules in which only certain occupational diseases are listed.—*Proc. 16th Ann. Meeting, Internat'l Assn. Industrial Accident Boards and*

Commissions, U. S. Bureau of Labor Statistics, *Bulletin 511*: 47-74 (Apr.), 1930.

Occupation and Health—Recent brochures in this "Encyclopedia of Hygiene, Pathology and Social Welfare, Studied from the Point of View of Labour, Industry, and Trades" have included the following:

- No. 189: Glass Industry
- " 190: Graphite
- " 191: Hides and Skins
- " 192: Iron, Pig Iron, and Steel Industries
Iron Carbonyl
- " 193: Ice-Cream Makers
- " 194: Lignite
- " 195: Dyeing
- " 196: Effort (Strain)
- " 197: Electrical Apparatus
- " 198: Electroplating
Emetine
Enamels, Enamelling
- " 199: Ethylene and its Derivatives
- " 200: Forges, Ironworks
- " 201: Horsehair, Bristles, and Hair
- " 202: Glove Manufacture
- " 203: Dock Labourers
- " 204: Dusts, Fumes, and Smoke
- " 205: Dyes

In Brochure No. 199, the articles for the *Encyclopedia* have been completed through the letter "E." Price of the complete Brochure Edition is \$16.00. International Labour Office, Geneva, Switzerland, 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Vitamin A Content of the Liver of Normal Hogs and of Hogs Developing Experimental Rickets—

This is a report of experiments planned to study the effect of lack of vitamin D on the storage of vitamin A when the diet was adequate in this vitamin. Since vitamin A has been found in greater abundance in liver than in any other tissues of the animal body livers were chosen.

Pure bred Duroc Jersey fall pigs from 7 different litters were used. They were divided into 2 groups each containing 5 males and 5 females. They were fed on a ration consisting of yellow corn, soy-bean meal, blood meal, dried skim milk and common salt. The control pigs had access to direct sunlight while those in the rachitic group were kept in pens in the barn. All the pigs in the control group survived the experimental period which was 129 days, while 3 of the pigs in the other group died.

The livers from the rachitic group were smaller, darker red, firmer and tougher than the livers from the controls; the rachitic liver showed 69.23 per cent moisture while the normal showed 69.99 per cent.

In this work rats 28 to 30 days of age and weighing from 30 to 40 gm., were used. The ration, consisting of one-third whole milk powder, two-thirds whole wheat, and salt to equal 2 per cent of the weight of the wheat, was irradiated 40 minutes.

The animals were kept on a vitamin-A-free diet until their weights remained stationary for 2 or 3 days. The rats were divided into 2 groups of 24 each, one group receiving 0.1 gm. of normal

liver, and the other 0.1 gm. of rachitic liver.

A table is given showing the weight curves. The rats on the rachitic liver averaged 6.27 gm. per week and those on the control, 4.15 gm. The rachitic hogs consumed approximately 62 per cent more food per lb. of gain and gained less than one-third as much in weight as the control. This points to the possibility that the rachitic animals because of slower growth were able to conserve and store more of the vitamin A supplied in foods.—Rebekah Gibbons and Charlotte B. Barney, *J. Home Econ.*, 22: 491 (June), 1930.

A Paratyphoid-like Infection Due to Morgan's Bacillus—

In a series of 49 cases, clinically resembling paratyphoid fever, *B. morgani* was isolated from the feces in all the cases, from the blood in 6 cases and from the urine in 11. It was the only significant organism in the feces. Agglutinins for the strain covered from each patient were present in his serum in significant titers (1:40–1:2,560). In 21 of the 22 cases where more than one specimen was obtained, the titer increased during the course of the attack. Agglutination tests with other organisms were invariably negative.

Three strains of Morgan's bacillus tested with 537 serums from normal persons and persons with other diseases agglutinated in 5 instances in a dilution of 1:20. As none of these serums agglutinated any of the strains in higher dilution than 1:20 the high titers observed in our series of cases are apparently the result of a specific reaction.

Examination of the feces of 2,798 healthy adults showed *B. morgani* in only 1.2 per cent. All 44 strains from our clinical cases proved virulent for mice, both on intraperitoneal infection and on feeding.—Leon C. Havens and Catherine R. Mayfield, *J. Prev. Med.*, 4: 179 (May), 1930.

A Comparative Study of Members of the Lactobacillus Genus, with Special Emphasis on Lactobacilli of Soil and Grain—Thirty-six strains of lactobacilli representing strains isolated from soil, grain, fecal material, milk products and dental caries are described. The media used and the methods of isolation are detailed. The fermentation reactions of the organisms upon 20 carbohydrates and related substances, their action in milk, broth and gelatin, and their acid production at four incubation temperatures, are listed.

Agglutination reactions and complement fixation tests of the 36 strains with antisera of representative strains are also listed, and results compared with fermentation reactions. Lactobacilli isolated from soil and grain did not as a rule ferment lactose. This marks them as a group distinct from *L. acidophilus*, *L. bulgaricus* and *L. odontolyticus*. Of the lactose non-fermenters, 4 types are more or less definitely indicated on the basis of their fermentation reactions.—George A. Hunt and Leo F. Rettger, *J. Bact.*, 20: 61 (July), 1930.

The Antiscorbutic Vitamin Content of Some Preserved Foods—This experiment was conducted to compare the antiscorbutic potency of certain preserved foods with that of the fresh. The foods investigated were canned and fresh grapefruit, packaged dates, canned pimiento, canned cranberry sauce and fresh cranberry. Guinea pigs, weighing 300 to 350 gm., were used as test animals, and the method followed was that of Sherman, La Mer and Campbell (*J.*

Am. Chem. Soc., 44, 165, 1922). The fresh grapefruit was fed as whole fruit and as juice only, and the canned as pulp only, liquor only, and pulp and liquor crushed together.

The protective portion of the canned grapefruit was found to be 2.2 to 2.8 gm. and the fresh 2 gm., while that of canned pimiento was 2 gm. When compared with the values given by Sherman in his *Chemistry of Food and Nutrition*, it is found these foods have vitamin C potency corresponding to that of lemon juice, orange juice, and raw or canned tomatoes.

Definite values for dates, and cranberries were not obtained since the animals refused to eat large enough quantities for a sufficient time, but the results which were obtained indicate that these foods are poor sources of vitamin C, although the raw cranberry is richer than dates and cranberry sauce.—Grace MacLeod and Lela Booher, *J. Home Econ.*, 22: 588 (July), 1930.

Significance of Colon-Aerogenes Group in Ice Cream. I. Survival of Members of the Escherichia-Aerobacter Group to Pasteurizing Temperatures in Ice Cream—This paper is a contribution to our knowledge of the proper interpretation of the significance of members of the *Colon-aerogenes* group when found in ice cream. It is pointed out by the authors that difficulties are met with in connection with this product which are not present when applied to milk. Some interesting data have been submitted which may be useful in interpreting the significance of members of this group of bacteria in ice cream.

Comparison was made of the effect on viability produced by heating the different cultures in skimmed milk and in ice cream at various temperatures for 30 minutes. It was indicated that the ice cream exhibited a greater protective action. The phase of the work reported

in this paper deals with the survival of members of the *Escherichia-aerobacter* group to pasteurizing temperatures in ice cream. The protective action of various ingredients of ice cream were compared when subjected to heating experiments.

As a result of their experiments, the authors conclude: (1) The critical temperature for *Escherichia-aerobacter* group in ice cream is about 65.50° C. (2) Ice cream has a greater protective action than skimmed milk for members of the *Escherichia-aerobacter* group when heated at temperatures of 60° C. and 62.80° C. for 30 minutes. (3) Thermal death point determinations made with the cultures in the different ingredients used in making ice cream failed to show any marked protective action of any one of the ingredients. (4) The susceptibility of bacterial cells to heat is greatly influenced by their age. Young cells are more readily killed than the older ones. (5) The ability of many strains of *Escherichia-aerobacter* group to survive a temperature of 62.80° C. and even 65.50° C. in ice cream should be taken into consideration when using the colon test as an index of the efficiency of pasteurization. (6) From the standpoint of the reduction in numbers of the *Escherichia-aerobacter* group pasteurizing the ice cream mix at a temperature of 65.50° C. is more desirable than the lower temperature, 62.80° C., which is the more commonly used.—F. W. Fabian and E. W. Coulter, *J. Dairy Sci.*, 13: 273 (July), 1930.

Vitamin-C-Content of Commercially Canned Sauerkraut Together with Some Observations on Its Vitamin A Content—This investigation was made to determine the vitamin C content of sauerkraut as it reaches the consumer. Six brands of commercial sauerkraut were used in the study of vitamin C. The protective method was

used with guinea pigs as the experimental animals. Levels of 7½, 5 and 2½ gm. were employed.

Considerable variation was found in the 6 brands. The first brand was outstanding because of the good growth and protection it afforded on the 2½-gm. level. The second brand, while giving good growth and protection on the 7½-gm. and 5-gm. levels, gave evidence of scurvy on the 2½-gm. level. The third, fourth and fifth brands gave evidence of scurvy on the 5-gm. level, while in the case of the sixth brand scurvy was evidenced not only on the 5-gm. level but also on the 7½-gm. level.

The vitamin C content of the second and third brands compared favorably with that of fermented fresh raw sauerkraut (this JOURNAL, 20: 326, Mar., 1930), but the third, fourth and fifth are distinctly less effective while the sixth contains about one-half as much of vitamin C as found in the raw sauerkraut.

Vitamin A was also studied but it was impossible to arrive at any accurate determination of the possible losses of vitamin A during manufacture and canning of commercial sauerkraut. The amount of vitamin A contributed to the diet by either sauerkraut or winter cabbage is negligible.—Bertha Clow, Helen T. Parsons, Ina Stevenson, *J. Agri. Res.*, 41: 51 (July 1), 1930.

Nutritive Value of Corned Beef in Rats—Feeding experiments were made on growing rats, in order to determine the nutritive value of corned beef. The experiments were divided into four groups, as follows:

- Group 1: Corned beef and salt mixture
- Group 2: Corned beef, salt and vitamin
- Group 3: Corned beef, salt and CaCO₃
- Group 4: Corned beef, salt, CaCO₃, and vitamin

The experiments lasted 190 days, and

on the 149th day the animals were paired. The animals of all groups developed without any apparent disorders. Special phenomena of avitaminosis were absent in all cases.

According to the growth curves, corned beef alone is a complete food only when supplemented with salt mixture. An addition of calcium is not able to make up the deficit but an addition of vitamins greatly improved the growth of the animals, and seems to insure an undisturbed development of the growing rats.

A propagative experiment was made to determine whether the nourishment of the animals of groups 2 and 4 was

entirely sufficient from every standpoint, notwithstanding the relatively good development of the animals. The experiment showed that additions to the food were still insufficient, and that with but one exception the animals did not propagate, due probably to a quantitative impairment.

It was not possible to obtain a perfect nourishment even by adding mineral substances and vitamins to the corned beef, although the vitamin addition was of great importance in connection with the corned beef nourishment.—Hans Bischoff, *Biochem. Ztschr.*, 222 Band, 1-3 Heft, p. 191 (June 16), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Results of Election at the Biennial Nurses' Convention in June— *American Nurses' Association—*

Officers—

President, Elnora E. Thompson, Portland, Ore.

1st Vice-President, Jane Van DeVrede, Atlanta, Ga.

2d Vice-President, Mabel M. Dunlap, Moline, Ill.

Secretary, Susan C. Francis, Philadelphia, Pa.

Treasurer, Jessie E. Catton, Boston, Mass.

Directors—1930-1934—

Mrs. Genevieve M. Clifford, Syracuse, N. Y.

Adda Eldredge, Madison, Wis.

Major Julia C. Stimson, Washington, D. C.

Ex Officio Members of the Board of Directors—

Elizabeth C. Burgess, New York, N. Y.

Sophie C. Nelson, Boston, Mass.

Clara D. Noyes, Washington, D. C.

National League of Nursing Education—

Officers—

President, Elizabeth C. Burgess, New York, N. Y.

1st Vice-President, Elsie M. Lawler, Baltimore, Md.

2d Vice-President, Anna D. Wolf, Chicago, Ill.

Secretary, Stella Goostray, Boston, Mass.

Treasurer, Marion Rottman, New York, N. Y.

Directors—1930-1932—

Nellie X. Hawkinson, Cleveland, O.

Carrie M. Hall, Boston, Mass.

Gladys Sellev, Chicago, Ill.

Ex Officio—

Mary M. Roberts, New York, N. Y.

President, American Nurses' Association.

President, National Organization for Public Health Nursing

National Organization for Public Health Nursing—

Officers—

President, Sophie C. Nelson, Boston, Mass.

1st Vice-President, Winifred Rand, Detroit, Mich.

2d Vice-President, Ruth Houlton, Minneapolis, Minn.

Treasurer, Michael M. Davis, Chicago, Ill.

Directors—Sustaining Members—

E. L. Bishop, M.D., Nashville, Tenn.

Haven Emerson, M.D., New York, N. Y.

Gertrude Peabody, Boston, Mass.

Dr. Miriam Waters, Los Angeles, Calif.

Directors—Nurse Members—

Amelia Grant, New York, N. Y.

Katherine Faville, Detroit, Mich.

Mrs. Anne L. Hansen, Buffalo, N. Y.

Florence M. Patterson, Boston, Mass.

Pioneering in Public Health Nursing in Italy—In 1919 the American Red Cross sent a special commission to Italy to study tuberculosis. Mary S. Gardner, "an authority on public health nursing in the United States," went as chief nurse of the section on public health nursing with 15 graduate nurses who had specialized in public health work to assist her.

Miss Gardner and her nurses had a stupendous task to perform. When the World War began, very few nurses in Italy had a training or status anywhere near that of the American or English nurse. Most of the nursing was conducted by the sisterhoods with the assistance of volunteers—men and women of the servant classes, who did the bedside nursing while the nuns directed the work and assisted some in the operating rooms. High standard schools of nursing were unknown and the hospital authorities did not favor founding any.

When the war came public spirited women in Italy took courses to fit them to care for the wounded soldiers, and these were indiscriminately called Red

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

Cross nurses. Their period of instruction required 1 month of hospital work per year, and at the end of 3 years the nurses received diplomas. There were other briefer courses in first aid and care of the sick and wounded. Public health nursing as we know it was unknown. The nuns did some home visiting but nursing care was secondary to spiritual solace and instruction.

The Italian volunteer nurses were devoted to their work, rendered splendid service during the war, and were well organized. At the end of the war this group was pliable and available for reconstruction work along more modern lines in nursing; and "schools adapted to Italian women and Italian needs, specializing in public health nursing, were established by Miss Gardner in Rome, Genoa, and Florence."

The problem was twofold:

1. The creation of a desire for the work, which meant that groups of Italian citizens had to be made conscious of the need for public health work.
2. The creation of a group of workers, which meant that a few carefully selected Italian women must be trained to act as pioneers and teachers.

These courses established in Rome, Genoa and Florence had good committees of public spirited Italian citizens sponsoring them. But there was difficulty finding practical field work for the trainees as most of the doctors would not tolerate "any system of nursing education permitting nurses to visit patients in their homes for follow-up work."

Other attempts had been made before to educate nurses in Italy along the lines of American and British training schools, but the opposition of the medical profession had blocked them.

However, the Italian Red Cross, which before had not recognized the need for a salaried or trained personnel, now decided to start training schools.

In June, 1919, Miss Gardner returned to the United States and Edna M.

Foley, Superintendent of the Chicago Visiting Nurse Association, took her place. "During her term of office the school at Florence was reopened and a second course was completed in Rome and Genoa," and positions were found for the nurse graduates of these courses in other Italian cities.

At the end of 1919 the American Red Cross withdrew from Italy after leaving money with which to carry on the nursing schools established. Well organized Italian committees were left to keep up the work and develop it.

Ten years after there is a very different picture. The work of the two American pioneers in Italy has borne wonderful fruit. There is a flourishing nursing school in Florence directed by an Italian trained nurse who also supervises the twenty visiting nurses in the city, graduates of the school. The public health nurses are called "assistenti sanitarie" and their "work radiates out from dispensaries, from their own offices or from the pharmacies where doctors hold their daily consultations. The nurses cover different districts and are assisted in many ways by committees of local importance which show great interest in their work." It is interesting to know that the fear and distrust of the doctors for these new public health nurses has almost entirely disappeared.

Two things have contributed to the present satisfactory status of public health nursing in Italy and to nursing schools established by the Red Cross:

1. The local committees were so well chosen and instructed in the pioneering period that the spirit of the American nurses lived on in the zeal and devotion of the Italian patronesses who fostered what they had begun.
2. The Fascist party emphasizes maternity care. In 1925 a law was passed requiring all Italian Red Cross volunteer nurses to return to Rome for an extra year of training at the Red Cross school.—

A Public Health Nursing Renaissance, *Red Cross Courier*, IX, 13: 12-14 (July), 1930.

Public Health Nursing Legislation—Recognition of public health nursing as a desirable or necessary function of government has only come about in the last 25 years.

Alabama was the first state to sanction the employment of public health nurses by governmental agencies; then New York state made it possible to employ tuberculosis nurses. Ohio, a little later, mentioned nurses in the school health inspection law. In 1911 Massachusetts permitted the employment of visiting nurses and Pennsylvania authorized the employment of school nurses.

The National Tuberculosis Association was one of the first organizations to urge employment of public health nurses.

In 1912 an increased interest began to be felt in visiting nurses and school nurses because of the influence of the newly formed National Organization for Public Health Nursing. Then after the World War the need for rural public health nursing work was recognized and this type of service was emphasized by the American Red Cross.

The Federal Maternity and Infancy Act of 1921 was a potent factor in stimulating interest in state departments of public health nursing. In 1920 there were but 7 state divisions of public health nursing and 11 divisions of child hygiene which were directed by nurses or which employed nurses who had the status of state nursing supervisors. Today there are 9 divisions of public health nursing and 24 divisions of child hygiene, 10 of which are directed by nurses and 14 of which employ nurses to direct the nursing activities of the state.

The establishment of the whole-time county health department has led to the passing of general health laws specifically mentioning the employment of public health nurses.

Now all but 8 states have legislation which pertains to the employment of public health nurses, and some of these have laws sufficiently elastic to provide

for needed personnel in public health work.

Eight states have specific laws defining public health nursing credentials, and 30 states have the nurses' requirements defined by their state health departments. Only 4 states specify that all public health nurses shall meet the requirements of the N. O. P. H. N.

Kentucky and New York are the only states in which the division of public health nursing was created by legislative action.

In public health nursing legislation so far experience has taught two principles:

1. Permissive legislation is usually preferable to mandatory laws.
2. There is an inherent difference in the customs, policies and constitutions of the states in different sections of the country. What is legal in one would be illegal in another.

It is believed that "legislation which delegates general authority to a specific department or agency is preferable to specific regulations in the statutes." The statutes are hard to change and salary and requirement schedules change in a growing profession. California's public health nursing law is considered one of the best examples of good legislation.

The Board of Supervisors of any county may employ one or more public health nurses each of whom shall be a registered nurse, possessing such qualifications as may, at the date of her employment, be prescribed by the State Department of Health. Her compensation and duties are to be determined by the Board of Supervisors.

There is a growing tendency to consider public health nursing as an integral part of a whole well-rounded public health program, not an isolated activity. (The growing interest and membership of public health nurses in the American Public Health Association is an indication of this.) They are feeling their responsibility in promoting every phase of the health program.—Pearl Melver, R.N., *Public Health Nursing Legislation*, *Pub. Health Nurse*, XXII, 7: 372-376 (July), 1930.

EDUCATION AND PUBLICITY

E. G. ROUTZAHN *

Old Dogs and New Tricks—The Extension Service of the U. S. Department of Agriculture furnishes information to farmers and frequently recommends the adoption of new methods.

Even as you and I, the department wondered how effective the "education," once loosed, might be. So 1,646 farmers on the department's mailing list, chosen at random, were followed up. Evidence that the department's recommendations had been adopted was surprisingly encouraging, but even more significant was the discovery that the age of the farmers who changed their minds and methods was apparently not a factor. Here is the tabulation according to age groups of those who adopted the advice.

Age group	Advice adopted
Under 30	76%
31-35	77%
36-40	77%
41-45	79%
46-50	72%
51-55	76%
56-60	71%
Over 61	66%

Farm women were similarly studied. They proved to be less easily influenced to change their household customs than were the men. This was especially noted in the group of women below 31 and above 45 years of age. Why this sex difference? Is it because women

are more conservative or more canny; or because farm men have, as the result of rapid advances in the farming industry, become more responsive to suggestions for change?

Health workers are frequently reminded that seed sown on adult minds falls on stony ground and that the older the mind the more rocky it is likely to be. The mind is, no doubt, most plastic during childhood, but age is apparently not a barrier to learning capacity or willingness to change one's habits—in farming!

The Laboratory Method—Various ingenious attempts have been made to teach health by laboratory methods. Nutrition is one of the few health subjects which lends itself well to experimentation conducted or participated in by the student. In the May, 1930, (Columbia) *Teachers College Record*, Mary Swartz Rose describes the methods devised over a period of 10 years for teaching nutrition in the fifth and sixth grades of elementary schools.

The general principles that should be taught, and why, are admirably discussed, but more interesting is the description of the teaching technic employed. For example: White rats kept in the school are fed on various diets. Daily, the children observe the animals, and soon plead that the ones on the poor diet be changed to the good one "because they look so pitiful." The children note not only the effects of diet but learn also to observe the signs of good

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to H. E. Kleinschmidt, Substitute Editor, 370 Seventh Ave., New York, N. Y.
Mr. Routzahn will resume his contributions to the JOURNAL with the November issue.

health, such as glossiness of fur, clearness of eye, pinkness of nose, and general physical vigor. Similarly, they notice the signs of failing health. The school cafeteria furnishes most pertinent object lessons. Milk is "taken apart" in the classroom. A chicken bone is decalcified in a jar of acid solution and serves to demonstrate visually the rôle of calcium in growth.

The article is pregnant with suggestions for those interested in teaching health by the visual and experimental methods.

Publicity That Paid—"Lottie, just past her eighth birthday, was playing house with two little friends. One was the father, one the mother, one the child. Mother at work in the next room heard some talk that sent her into the playroom in horrified, terrified haste."

So began one of Angelo Patri's recent syndicated articles under the caption, "Innocent Children." Parents interested in sex teaching were advised to write to the American Social Hygiene Association for help. Within twenty-four hours, the astonished association was flooded with letters—at this writing they total 3,500. What was the pulling force of this article?—the personality of Patri?—the reputation of the association?—or the simple, intimate account of an experience familiar to every mother? In the May, 1930, *Journal of Social Hygiene*, you will find an interesting editorial which quotes the article, comments on the types of letters received, and explains how the replies were handled.

The Newspaper Man Tells 'Em—The *Indianapolis News* published a series of articles written by its special correspondent, Harold C. Freightner, describing the different departments of state government. Seven of the installments informed the people in interesting style what the state board of health is

for and what it does. When a health officer or his assistant talks shop publicly, the listeners are usually few, and the more enthusiastic the talk, the tighter are their fingers crossed. The disinterested observer, "looking in" on the department, has a better hearing. Health leadership is dependent on the appreciation and understanding of the people as to what the health department is driving at. Indiana's achievement is worthy of emulation. The articles are being reprinted in current numbers of the Indiana Health Department's *Monthly Bulletin*.

Can Doctors Write?—Is it true that the doctor is incapable of telling the layman health facts interestingly? Health workers frequently complain that it is. In Toledo, O., the local medical society, through its Education Committee, conducts a medical column in the *Toledo Times*. Experience proves that the column is widely read. About 400 of the published essays have been reprinted in book form, called "Three Minute Medicine," under the authorship of Dr. Louis R. Efler, Director of Education. A preface tells the story of this enterprise and discusses the principles of health education as they involve the public, the press, and the doctor.

Brevity and compactness characterize the essays; none of them exceeds 400 words in length. In almost every article, the layman's taste for the spectacular in medicine is capitalized by citing some scientific curiosity. Then he is adroitly led directly to the meat of the essay, which consists almost invariably of a single idea or concept. Who could resist such captions as: "Osler and Chloroform," "Dr. Murphy and the Murphy Button," "Lawsuits in Medicine," "Catgut," "Manana," "The Great Hernia Mystery," "Sword Swallowing and the Esophagoscope," "Contortionists and Dislocationists," "Ven-

triloquism." Technical expressions do creep in here and there, but on the whole the language is simple, pithy, and picturesque, the sentences are short, and the information is scientifically sound.

In a private communication, the author generously authorizes republication of these essays if sponsored by reputable organizations.

The Health Specialist—Dr. J. H. J. Upham, eminent internist and medical teacher, believes that the public should be taught to regard the health officer as a specialist of a very important branch of medicine. He was speaking to county and city health commissioners of Ohio at their annual conference at Columbus, May 19, 1930. He believes that the people have a deep-seated confidence in scientific medicine and will accord the health officer the same recognition they give a specialist in any other branch of medicine and pay him accordingly. This attitude will also enlist the sympathetic understanding of the private practitioner; corps spirit will prompt the doctor to support the health department and to explain to patients the necessity of health regulations. It will also, Dr. Upham believes, attract good men into the public health field. Dr. Upham's paper was reprinted by the Ohio Public Health Association, 72 South Fourth Street, Columbus, O.

A Notable Exhibit—Practically every one of the 4,400 nurses who attended the biennial nursing convention in Milwaukee, June 9 to 13, visited the Industrial First-Aid Exhibit. It consisted of three compartments; first aid room, office, and rest room. The walls

were finished in spotless white, the floors were covered with linoleum. Not only was the equipment complete in every detail necessary to care for injuries, but there were on display objects and models useful in teaching health practices to employees. The shoe exhibit, for example, illustrated types of footwear suitable for workmen in various occupations. On the shelves were books for employees and nurses. Two nurses were in attendance as demonstrators. Record forms were distributed free to visitors.

This unique display owes its success largely to the genius of Johanna Johnson. It was sponsored and paid for by the Employees' Mutual Life Insurance Company, the Cellucotton Products Company, and other manufacturers who contributed special supplies. The exhibit stimulated considerable interest in the industrial nursing project of the N. O. P. H. N.

The Lecturer's Man Friday—The Society for Visual Education announces a new projection apparatus which weighs only $1\frac{3}{4}$ pounds. This machine is a small stereopticon which uses 35 mm. safety stock film for showing still pictures. It has a capacity of 100 frames or pictures without reloading. It is so compact that it fits easily into the coat pocket. A dozen or more spools of film may be carried in one's other coat pocket if necessary. It projects pictures of a reasonable size in a semi-darkened room. The itinerant lecturer who will not be bothered with undue baggage and accessories will find this a good helper. It is called the S. V. E. Jam Handy Pocket Explainer.

BOOKS AND REPORTS

Handbook of Physical Education—
By Ernest G. Schroeder. New York: Doubleday, Doran, 1929. 323 pp. Price, \$2.00.

The book is divided into two parts. Part I contains ten brief chapters on (1) Objectives, (2) Suggestions for the Instructor, (3) Organizing a Program, (4) Marching, (5) Calisthenics, (6) Games for Outdoors and Indoors, (7) Miscellaneous Activities, (8) Intramural Athletics, (9) Corrective or Medical Gymnastics, and (10) Wrestling. Part II, comprising nearly two-thirds of the total book, is also made up of ten chapters, nine of which are devoted to apparatus work and one to tumbling.

Since this purports to be a handbook of general physical education the reader is likely to be surprised at the disproportionate amount of attention given to formalized activities, such as marching, calisthenics and apparatus work, and the meager treatment given sports and games aside from wrestling. Mr. Schroeder, however, seeks to justify his position by stating on page 127:

A survey of physical education programs in our high schools has revealed that apparatus exercises as a means of physical education is being neglected in our schools. The tendency seems to be to a program limited to sports and games.

Perhaps also the fact that Mr. Schroeder has been director of the gymnasium at the State University of Iowa for 23 years, during which time he has been a leading figure in the advancement of the Western Intercollegiate Gymnastic, Fencing and Wrestling Association may account in part for this conspicuous treatment. These factors superimposed on his earlier experiences as an expert gymnast and wrestler in Ohio Turn-

verein circles present a uniform background with which his philosophy of physical education as here expressed is in full conformity.

A very limited treatment of Intramural Athletics, confined to ten pages, and the chapter on wrestling, featuring the holds commonly used in intercollegiate and interscholastic wrestling contests, are the chief deviations from the formal program. The chapters on apparatus work are especially well done, covering a course of progressive lessons on various pieces of apparatus. The chapter on Parallel Bars, for example, containing 54 graded lessons, illustrated and descriptive of the wide variety of standard combinations commonly used on this piece of apparatus, may be taken as typical of the excellent manner in which Part II is done. The objective character of the volume as a whole would be enhanced by definite reference citations and more extensive and annotated bibliographical material.

The book should be valuable to teachers whose work includes the activities treated and for those who cannot afford specialized books for each. It will also be welcomed by those who, with Mr. Schroeder, believe that the formalized activities are an indispensable part of an all round Physical Education program.

F. W. LUEHRING

Mental Hygiene—Special International Congress Number, April, 1930.
Price, \$.75.

This issue of a well known journal cannot be passed by without special mention. As the subtitle shows, it was issued on the occasion of the First International Congress on Mental Hygiene recently held in Washington, D. C. If one had not previously realized the im-

portance of mental hygiene, this issue would surely convince him.

It opens with a chapter by the Editor on "Finding a Way in Mental Hygiene," and the other articles are of the usual high quality which characterizes this publication. There follows a section made up of cabinet size photographs of the officers of the national societies taking part in the Congress. More interesting even than this, is the third section, devoted to the pioneers in mental hygiene. Here we have pictures of practically all of the great men of the past, beginning with Pinel, Tuke and Chiarugi. Accompanying each photograph is a short biography. Ninety-one pages are devoted to book reviews, among which are some of unusual interest.

It would be hard to speak too highly of this volume, for so it is, rather than an ordinary issue of a current magazine. We congratulate the Editor, as well as the National Committee for Mental Hygiene.

M. P. RAVENEL

Fundamentals of Bacteriology—By Charles Bradfield Morrey. (4th ed. rev.) Philadelphia: Lea and Febiger, 1929. 347 pp. Price, \$3.50.

This is the fourth edition of a textbook of bacteriology intended to be used during the first or introductory quarter's work. It is therefore elementary in nature, and does no more—nor less—than its title promises. The author presumes no previous scientific knowledge on the part of the student, and presents each subject in a clear simple manner. About three-fourths of the book is devoted to morphology, physiology, and methods of study. Where details of technic are not given, as in the discussion of single cell methods, references are cited. The discussion of hydrogen ion concentration is especially good.

The last quarter of the book gives a general survey of pathogenic bacteriology, ending with a brief history of the

science. There are many illustrations showing cultures and apparatus, and five plates of portraits of famous bacteriologists. There is an adequate index.

As an introductory text this seems quite satisfactory. GRACE ELDERING

Incapacity or Disablement in Its Medical Aspects—By E. M. Brockbank, M.B.E., M.D., F.R.C.P. London: H. K. Lewis & Co., 1926. 120 pp. Price, \$2.00.

Medical practitioners in examining persons of both sexes for reports upon their fitness for employment in various capacities frequently have to take part in legal proceedings involving statements as to complete or partial disablements. For this it is very useful to have at hand some elementary information on the law of the subject with opinions from medical and surgical authorities on the effects which injury may have in producing various illnesses. The decisions of courts have been consulted in these matters. Discussion of deleterious or dangerous trades, however, has been omitted from the present work.

The book comprises chapters upon the meaning of incapacity, its causes and varieties, the disabled worker's chances of employment, and pension schemes in relation to the employer, the worker, and the insurance companies, with special reference to the National Health Insurance Act.

The main theme of the book is the discussion of the more common causes of incapacity or disablement arranged in alphabetical order for (we have counted them) some 77 afflictions, beginning with Age, Albuminuria, Anemia, Aneurysm, etc., to Thyroid Gland, Tuberculosis, Varicose Veins, and Vertigo. Many cross references are made although the index is brief. We note that, under *mastoid disease*, otitis media is not considered incapacitating for laborious

work, while *pregnancy* in normal women accustomed to hard work may not interfere with manual labor until within a week or so of full time. *Mitral stenosis* incapacitates for laborious work. Good wages ward off *neurasthenia*. Insurance acts should provide for mothers suckling their babies every 3 hours in the interests of the baby.

This well written little volume contains much valuable information in brief form, especially for those interested in prognosis in the afflictions of workers, and is by the author of a previous volume, *Life Insurance in General Practice*.

EMERY R. HAYHURST

Hygiene for Nurses—By *John Guy and G. J. I. Linklater*. New York: Wood, 1930. 212 pp. Price, \$1.75.

This book has been modelled on the syllabus issued by the General Nursing Council of Great Britain. The authors have curtailed the description of the communal aspect of hygiene because they think that hitherto too much stress has been laid on it in the teaching of nurses, and have concentrated on the personal aspect, emphasizing especially the hygiene of the new-born and dietetics.

In the chapter on Communicable Diseases, under Smallpox is a good history and exposition about vaccination, but in describing diphtheria not a word is said about either antitoxin or toxin-antitoxin. This is rather a serious omission. There seems to be a little too much emphasis placed on terminal, and not enough on concurrent, disinfection.

Under Personal Hygiene an unusually interesting and instructive description is given of clothing and cloth materials. The chapters on Food and Metabolism, and Vegetable Foods and Animal Foods are excellent. In the appendix also are helpful tables giving the percentages of foodstuffs in different animal, vegetable, and other foods.

There are a few minor details with

which one might disagree, but on the whole the book is up-to-date and excellent, and can well be recommended as a text or reference book for nurses. It will give them a public health point of view greatly needed today. It has the added attraction of being well printed and easy and pleasant to read.

EVA F. MACDOUGALL

Rest-Pauses in Industry—By *S. Wyatt, M.Sc., M.Ed.* London: H. M. Stationery Office, 1927. 21 pp. Price, \$50.

This is a review of the results obtained by the investigator, S. Wyatt, M.Sc., under the Medical Research Council, in which there are taken into consideration such features as the best position for a rest spell in the midst of the morning and the afternoon work periods—in which it is concluded that the rest pause should be given at the time the output has just reached its maximum. Likewise if a marked decrease in production again occurs a second pause should be introduced where output again begins to decrease. The length of the suggested rest pause should be such as not to cause the loss of swing or incitement, nor more than enough to dispel the factors which have been impeding working capacity. The amount of rest necessary for complete recovery, the method of using rest pauses, the relation to the nature of the work, etc., with objective and subjective effects, are briefly discussed.

The effect of a rest is particularly beneficial in repetitive work of a monotonous character, with the influence most marked on work requiring the greater activities, also where natural rhythm is upset. Benefits of rests may even be noticeable before the rest occurs.

However, unscientific methods have too often muddled the findings of rest period studies so that a careful investigation of the work itself and a typical

curve of output should be obtained before rest periods are introduced anywhere. The effects are also more favorable with some workers than others, and one rests better when all others are also resting at the same time.

Variation of activities is not stressed here nor does it seem that the investigator has considered the value of the short-intervalled rest pauses that must constantly occur between individual work efforts, from which it is just conceivable that if these were properly regulated they might be more effective than definite rest periods. The ideal day's work is one in which the worker quits fresh, and not, as Sir Thomas Oliver long ago remarked, "so tired."

EMERY R. HAYHURST

Proceedings of the Seventh Annual Short School—*Texas Association of Sanitarians, Edinburg, Texas, December 3-5, 1929.* 107 pp. Price, \$1.00.

This seventh proceedings has in it the usual number of short articles on various phases of sanitation. Health education, publicity and administration; garbage incineration; swimming pool and beach sanitation; rodent control; an oyster survey; and the relation of aviation to health are included in the first section.

The second part is devoted to milk. Pasteurization is discussed by Putnam in a very good article. Bovine infectious abortion, T. B. testing, dairy waste treatment, dairy barns and milk houses, as well as water supplies and sewage treatment devices therefor are touched upon.

ARTHUR P. MILLER

Immunity in Infectious Diseases—*By A. Besredka. Translation, Herbert Child. Baltimore: Williams & Wilkins, 1930.* 364 pp. Price, \$5.00.

However the author may seek to justify the publication of this book, the reviewer can see little if anything to warrant its presentation. It is essentially

a reprint of Besredka's publications without the virtue of having these brought up to date or even commented upon in the light of modern immunology. Approximately half of the book is devoted to a discussion of antivirus and its clinical use, a subject well covered in Besredka's earlier book, *Local Immunization*. There is insufficient new material to pay for the pain of reading 364 pages, rather poorly written, and indifferently translated. The character of the contents, the title, in fact, everything about the work, suggests d'Herelle's book, *Immunity in Natural Infectious Disease*. It is, however, entirely lacking in the charming style, excellent translation and thought compelling contents of that work.

The character of the production is well illustrated by Chapter IV entitled Antistreptococcic Serotherapy. The most recent reference quoted in this chapter is dated 1909 and the concluding statement is this: "All these experiments . . . indicate that henceforth the streptococcus cannot be looked upon as the actual cause of scarlet fever. . . ." While there may be those who share this opinion, their belief is based upon discoveries much more recent than 1909. As science it has little value, as history it is woefully lacking, and since it cannot qualify as good reading material it is difficult indeed to determine its value.

N. W. LARKUM

Health, Public and Personal—*By Ralph E. Blount. Boston: Allyn and Bacon, 1930.* 347 pp. Price, \$1.20.

A new edition of this conveniently sized book has appeared. The book is of an elementary character but it was so designed by its author, as in the writing of it he had in mind the fundamental things of public health which a pupil in the higher grades of the elementary schools or in high school ought to know or be taught. The writer shows an up-to-date knowledge of the main facts of

physiology, anatomy and bacteriology, and relates what is said of personal and public health to that knowledge, which is desirable in such a handbook, not only for accuracy of statement, but for student instruction.

The position taken by the writer in regard to what is based on the best knowledge of the day as against the theories of quacks and the pseudo-scientific is one that commends itself to the medical profession and to the trained public health educator; viz., that it is always wise to consult the best medical opinion rather than fly to some fad that may have no scientific or rational basis.

The book is well written, attractively illustrated and is worthy of a place among books listed in the calendar of studies for elementary and secondary schools.

The advice given is generally sound, although some might question, for example, the advisability of telling people when they are wounded to treat the wound with iodine or some other antiseptic. This may be desirable at times but not infrequently the application of antiseptics causes the individual to do nothing more for the wound when something more should be done. Besides, the use of antiseptics may mask the condition if the individual seeks surgical attention.

JAMES W. WALLACE

Lehmann's Medical Hand Atlases—

Determinative Bacteriology, Vol. I: Atlas. By K. B. Lehmann of Würtzburg, Germany, and R. O. Neumann of Hamburg, Germany. English translation by Robert S. Breed, Geneva, New York. Seventh German edition, 1930. (Second volume to be published September, 1930.) New York: G. E. Stechert (Alfred Hafner), 1930. 71 pp. 64 ill. Price, \$12.50.

This is the seventh edition of the Lehmann Medical Hand Atlas issued originally thirty years ago.

The book is divided into three major sections, Bacteriological Technique, General Diagnosis, and Atlas. These three sections include the best bacteriological information available, as well as a series of fine color plates and drawings.

The section of Bacteriological Technique consists of 83 pages of meaty and concise information, microscopical technique, staining solutions, preparation of stained specimens, media preparation and methods of use, animal investigations, bacteriological examination of air, water and soil, and the most important immunological-biological diagnostic procedures are covered thoroughly. Over 2,000 new citations have been introduced, so that the section is replete with references.

The section on General Diagnosis is an introduction to the methods of determining bacteria from the plates in the *Atlas*. In outline, the method consists of using the appearance of the stained organism under a magnification of 1,000 diameters, the macroscopic appearance of gelatin plate colonies, the appearance of the gelatin colonies under a magnification of 60 diameters, and the appearance of the gelatin stab. An example is included showing in detail how bacteria are identified.

The *Atlas* consists of 64 excellent color plates and drawings to be used in the application of the method of general diagnosis outlined above. The authors have used color plates for such objects as the stab, streak and potato cultures; drawings for colonies on plates and photographs for bacterial smears. With this combination illustrations of splendid accuracy are presented throughout the whole book.

The English translation makes this compendium available to a great number of English reading scientists. The print is fine but easily readable. Except for two plates which are bound in upside down, the book is well put together.

G. D. CUMMINGS

Stories of Health and Happiness—

By Elizabeth Blaine Jenkins, with the coöperation of Dr. C.-E. A. Winslow. New York: Merrill, 1929. 163 pp. Price, \$.68.

This little book of attractive stories with quaint illustrations certainly should accomplish something in the way of interesting young children and—quite possibly—older ones as well, in health habits. The ten stories deal with the commonplaces of health education—exercise, food, sleep and the rest—but in a far from commonplace manner.

Fairy tales may be what the old fashioned "health agent" would call them, with a scornful sniff, but if they succeed even in part in inculcating honest-to-goodness health habits and attitudes in the young (not the sort of imitation most adults have), they will have made a real contribution. It may well be that the success of the public health movement of the future will depend largely upon health habit promotion among the preschool and younger school children; and to reach the youngsters one must talk their language.

MERRILL CHAMPION

The Baby's First Two Years—By Richard M. Smith. Boston: Houghton Mifflin, 1930. 159 pp. Price, \$1.75.

The new revised edition of *The Baby's First Two Years*, by Richard M. Smith, is just the book a pediatrician would like to see in the hands of his young mothers. It does not attempt to discuss the diseases of infants as do so many similar books, but gives clearly and definitely just how a normal infant should act and how it should be cared for.

The definite way in which he expresses the details should be especially praised as a new mother wants to know exactly how many diapers and shirts to buy, at what temperature to have the water, exactly how to wash the baby's

eyes, etc. In the diary of "a typical day" at the end of the book, the mother will find every detail of infant care outlined for her. Incidentally the pediatrician who puts the book in her hand will find himself saved many needless telephone calls.

The chapter on "bottle feeding" emphasizes the two main factors in artificial feeding:

1. The absolute necessity of either pasteurization or boiling of milk with preference for boiling
2. Necessity of fitting the formula to the infant; that is, not to feed it by rule of thumb, but only according to the doctor's prescription

I also wish to praise Dr. Smith's definite stand for the 4-hour interval between feedings and the early elimination of night feedings. I find him a little conservative as to the time at which potatoes, butter, and eggs should be introduced into the diet, but the book as a whole is so excellent I will not quarrel with him over a few months.

LUCILLE LIBERLES.

Ergebnisse der gesamten Tuberkuloseforschung—Herausgegeben von H. Assmann, Leipzig; H. Beitzke, Graz; H. Braeuning, Hohenkrug-Settin; St. Engel, Dortmund. G. Thieme Verlag, Leipzig, 1930. Vol. 1, viii + 573 pp., 110 figs. Price, M. 42.00, Bound, M. 45.00.

The purpose of this new reviewing periodical is to present at such intervals as the growth of the literature warrants critical summaries of the world's literature upon tuberculosis. The papers in this field are widely scattered in medical journals in various languages and in diverse fields. Significant papers in all phases of the subject are to be included. The subject matter in hand will provide for two volumes, the current one and another to be issued shortly. It is the aim to include the ~~clinical~~ ^{clinical} ~~pathological~~ ^{pathological} ~~anatomy~~ ^{anatomy} ~~bacteriology~~ ^{bacteriology} ~~diology~~ ^{diology} ~~serology~~ ^{serology} ~~immunobiology~~ ^{immunobiology} ~~ther-~~

apy in all its branches, and the legal and social aspects of tuberculosis. The viewpoints of the scientific investigator and the practitioner are presented.

The first volume contains chapters on the early diagnosis of tuberculosis by Dr. Felix Klemperer, early infiltration by Dr. H. Assmann, healing processes and the detection of healing in roentgenograms in pulmonary tuberculosis by Dr. F. Fleischner, protective immunization against tuberculosis by Dr. B. Lange, the allergy problem by Dr. F. Redeker, the biological bases of the most important non-specific blood reactions in tuberculosis by Dr. G. von der Weth, the detection of the tuberculous and the fight against tuberculosis by Dr. H. Braeuning, the social relations of tuberculosis by Dr. F. Ickert, and the localization and roentgenological demonstration of primary tuberculous lesions in the lung by Dr. S. Engel.

The volume has very complete author and subject indexes. C. A. Koroi

Getting Well and Staying Well. A Book for Tuberculous Patients, Public Health Nurses, and Doctors—By John Potts, M.D., with an Introduction by J. B. McNight, M.D. (2d ed.) St. Louis: Mosby, 1930. 221 pp. Price, \$2.00.

Dr. Potts has written a book that is so helpful to many and so invaluable to a certain class of patients that a second edition is welcomed. The burden of the book is that early diagnosis is usually followed by successful results. It has become a habit to blame the doctor first consulted, usually the family doctor, for his mistakes in not suspecting and diagnosing pulmonary tuberculosis in its earliest and most curable stages. The author very justly points out that many patients are already in a more or less advanced stage when they first seek medical advice.

In his first chapter, Suspecting Tuberculosis, he emphasizes this and draws

attention to certain symptoms that should cause any person to suspect tuberculosis: ease of fatigue, irritability, fickle appetite, uncertain digestion, pain or soreness in the chest, poor recovery from "something." Such symptoms are especially important between the ages of 18 and 28. He further emphasizes the importance of "feeling tuberculous," which he apparently applies to the indefinite sense of unease or malaise.

There is only one sure solution of the problem: the lay people must know how to suspect the disease in themselves.

It is a great pity that not more of those who are to become tuberculous in the next few years can have an opportunity to read all this. The section on diagnosis will probably be of more aid to the general practitioner than to the patient, but his references to finding out Who's Who in medicine and referring the patient to the state sanatorium for this knowledge is excellent advice.

Doctors can furnish information only to persons who want to learn. If people want to remain ignorant of the subject and run the risk of paying a severe penalty because of their ignorance, it is their privilege to do so.

Why, asks Dr. Potts, if a boy can read a lesson in his school reader about "Frank and the Bear," should he not read about "Frank and the Mosquito"?

The sanatorium is praised, but attention is called to the fact that the majority of all patients must sooner or later undergo home treatment and they and the family must learn what to do, for recovery involves years of curing. The three arch enemies of the patient are the ignorant family, the officious and ignorant friend and the quack, all described in no uncertain language. Attention is called to the necessity of facing disagreeable facts.

Much of the success or failure of a tuberculous person, provided he has had the advantage of an early diagnosis, depends upon whether he will face the facts like a grown person or act like a child.

There is little to criticise in the book. It might be well to call attention to the value of rest after the noon meal for those undergoing treatment as well as for those who have later returned to work. Such rest is particularly important for those past 40.

It is always a question whether it is a wise policy to write a book for both patient and physician but the author has never lost sight of the patient. It would possibly be a trifle fairer to the doctor if it were mentioned that the "tuberculous feeling" can occur in other conditions but in these it rarely,

as the author states, continues so long.

While few states have no state sanatorium, it might, however, be a wise thing to refer patients seeking information in regard to Who's Who in medicine to the National Tuberculosis Association's headquarters in New York. Some would not follow Dr. Potts in omitting taking the temperature at 8 p.m. and the use of practicing diaphragmatic breathing. These criticisms are, of course, of little moment and in no way impair the very considerable value of this book.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Rockford, Ill.—This city with a population of 85,600 reports a resident death rate of 8.7, a birth rate of 17.2, and an infant mortality rate of 48.9. The report is attractively illustrated with charts and graphs carefully prepared, together with a few photographs. A classified financial statement indicates an expenditure of \$30,655 by the Health Department during the year.

"Publicity and education of the public is a necessary function of a well organized department of public health." It is noted in the Bureau of Education and Publicity section that 25,190 health pamphlets were distributed, together with 2,600 educational letters and 1,802 birth certificates. There were 205 press articles and 48 lectures recorded, while 132 health posters and 52 charts, maps and graphs were used. It is noteworthy that the health officer devotes 5 pages to the work of the Visiting Nurse Association, a voluntary agency, in order to present a complete picture of nursing service in the community.

Manchester, N. H.—The communicable disease incidence was relatively low during the year. A neighborhood outbreak of diphtheria is discussed and attention is called to the fact that no child who had received toxin-antitoxin previous to the epidemic developed diphtheria, although a few children so immunized were directly exposed. "It is also significant that many parents who in former years had steadfastly refused to have their children treated, not only asked but even demanded immediate treatment."

An infant mortality rate of 93.2 is recorded. Three infant welfare stations report 2,819 babies under supervision during the year, with 14,830

home calls. A birth rate of 16.9 and a death rate of 10.9 are recorded.

Dairies from which milk was shipped into the city were inspected at least once and sometimes many times during the year. It is reported that so many requests for ratings of milk sold by dealers have been received that a schedule has been devised, and if satisfactory, it will be distributed to those who are especially concerned with the care of babies and infants.

New Hampshire—A report of the Tuberculosis Association for the year 1929 shows that the volume of work accomplished has been larger than in any previous year. Seventy-eight clinics were maintained by the association with 298 sessions. There were 5,862 patients under treatment and supervision. This includes 2,780 arrested cases, 680 of which were added this year, and 8,249 physical examinations were given. Besides these clinics 48 school clinics were held when 2,906 children predisposed to tuberculosis were examined and treated. Since 1925, 13,941 possible victims and 400 with symptoms have been examined. Large numbers of undernourished children have been treated and cured. There were 106 children sent to summer camps last year. The association nurses made 21,784 visits.

A campaign for early diagnosis of tuberculosis in children was begun in April. The purpose of the campaign was to instruct the parents and also to teach the children in school. During April 6,500 pamphlets were distributed and \$1,100 was spent for posters. It sponsored health clubs for children, health education of industrial workers, and play writing contests. The associa-

tion provided a 2-page bulletin of information regarding the diagnosis and treatment of tuberculosis for the physicians of the state, prepared and published by the National Tuberculosis Association.

The state appropriated \$60,000 for the 2 sanatoriums for maintenance and additional beds. During 1928 the Association collected \$41,023.75 from Christmas Seals.

Knoxville—A creditable report of 81 mimeographed pages, for the year 1929, shows graphically the work of the bureau of health of the Department of Public Welfare of Knoxville. The table of contents is followed by a concise summary of the organization and special features of the work of different divisions. Knoxville is governed by a mayor and city council, which elect a business manager, who in turn appoints five directors of the following departments: Law, Finance, Public Safety, Public Service, and Public Welfare. During 1929 the city appropriated from public funds slightly less than 62 cents per capita for public health protection.

During the past 3 years the bureau has conducted an extensive study of over 27,000 separate premises in the city, and the results have been recorded and filed. The analyses of these data in preliminary form make this report of unusual interest to administrators. The Bureau of Health, the State Department of Public Health and the Department of Hygiene of the University of Tennessee participate in an annual program of training of sanitary inspectors which deserves careful study. During the year nuisance abatements increased 24 per cent over the previous year and 78 per cent over the 1925 experience. Much progress has been made in the extension of sanitary sewers since the ratification of a 2 million dollar bond issue in 1928.

Improvement in the milk supply is noted over the 5-year period of supervision under the Standard Milk Ordinance of the U. S. Public Health Service.

During 1929, 560 dairies supplied this city of 108,700 population with over 12,000 gallons of milk, 61 per cent of which was pasteurized.

The generalized plan of public health nursing was adopted in 1925 when several separate groups were consolidated under the Bureau of Health. School nursing is one of the important items in the program.

New York Tuberculosis and Health Association—In 1929, 100,000 people were reached directly with personal service or information on health matters by the New York Tuberculosis and Health Association, and at least 1½ million more were helped through services to clinics and sanatoriums, according to the annual report of the Association.

The health education service of the association during the year arranged 585 lectures (reaching 67,000 people), 232 radio talks and 1,369 motion picture showings, with a total attendance of 648,000. The association helped in the city-wide Health Examination Campaign of the County Medical Societies.

Service was given to the tuberculosis, heart and other clinics of the city. The income and cost of living of families bringing their children to baby welfare clinics were studied; surveys were made of the out-patient departments of several large hospitals. The clinic committee of the association, according to the report, is the only public health organization prepared to give these expert services.

The Research Service of the association constantly analyzes the city's sickness and death records, and in 1929 helped in a study of tuberculosis mortality in negro sections of Harlem; co-operated in several studies with the Welfare Council; joined with the Bellevue-Yorkville Health Demonstration in various studies; took part with the

Committee on Neighborhood Health Development in studying suitable locations for the new Department of Health local health centers. A city-wide survey of the prevalence of venereal disease was directed by the Social Hygiene Committee of the Association.

A study of silicosis and tuberculosis among rock-drillers, blasters and excavators was completed, and the association is actively coöperating in formulating preventive measures. Further studies are planned of the hazards affecting many of the 600,000 industrial workers of the city. Many of these hazards eventually lead to tuberculosis, pneumonia, heart disease, lead poisoning, and other occupational diseases. An Industrial Advisory Committee organized in 1929 assists mercantile, industrial and other establishments in studying their industrial health needs and organizing medical departments.

During 1929, thousands of tuberculosis patients were helped to secure sanatorium or clinic care; children with heart disease were placed in suitable jobs, given vocational scholarships or placed in convalescent homes; mothers and babies were cared for in well baby clinics; thousands of industrial workers and others were helped to secure health examinations; over 5,000 workers and children were given dental care at cost in the demonstration clinics of the association.

Pennsylvania Tuberculosis Association—The 1929 year book refers to the society, organized in 1892, as the oldest tuberculosis prevention organization in the world. The second Early Diagnosis campaign was considered one of the most valuable projects of the year. Members of the Outdoor Advertising Association coöperated in posting approximately 700 twenty-four sheet posters in various sections of the state. Railroads placed 10,000 posters in stations, shops and offices; distributed to

employees 40,000 pieces of literature and to railroad physicians 1,000 copies of a leaflet regarding the diagnosis of tuberculosis. The State Department of Labor and Industry distributed 10,000 posters, and the same number of copies of the leaflet "Make Sure." The State Manufacturers Association sent 6,500 posters to its members. Insurance companies coöperated in a somewhat similar manner.

The report contains effective charts, and a description of two tuberculosis studies of programs in the state. The Christmas Seal Sale in Pennsylvania in 1928 resulted in the raising of a total of \$599,813, with a per capita sale of \$6.09 as compared with \$5.93 in 1927.

Mount McGregor Sanatorium—The Metropolitan Life Insurance Company maintains a sanatorium at Mount McGregor, N. Y., for the benefit of employees. According to the 15th annual report for 1929, 5,558 patients have been admitted since the opening in November, 1913, of which 2,588 were tuberculous. The average daily census for the year was 260, with a total of 94,900 patient days. Three hundred patients were admitted in 1929, 163 having tuberculosis, all but 2 being pulmonary in type. The percentage of incipient tuberculosis cases on admission was 31, of moderately advanced 45, and far advanced 23, the latter group being somewhat larger than usual. The number of tuberculous patients coming from the field is slightly larger than that from the home office; by far the greatest number of non-tuberculous patients are from the field (79 per cent).

Maryland—The 1929 report of the Bureau of Sanitary Engineering of the Maryland Department of Health covers 16 mimeographed pages of interesting public health engineering material. Attention is called to the typhoid death rate which in Maryland, outside of Bal-

timore City, has fallen to approximately one-ninth of what it was in 1910. The rate for the entire state was 4.2; for Baltimore City alone, 3.2; and for Maryland exclusive of Baltimore, 5.2. To maintain this condition, emphasis is given to the necessity of exercising all sanitary control at maximum efficiency.

Progress is noted in efforts to improve the operation of water purification plants and to secure the extension of sewage disposal systems. Sanitary inspections are made of schools, water sheds, swimming pools, and camps. Appropriations of the 1929 Legislature have made possible improvements in water supply and sewerage systems at state institutions. Extensive studies of stream pollution and industrial wastes are recorded, in addition to an oyster survey. Field inspections during the year totalled 2,068, while 6,486 samples were collected, 208 permits were issued, and 92,680 miles were travelled by members of the staff.

Miami County and Troy City, O.

—The 1929 report contains graphs and charts to show the organization of the health department and the downward trend of tuberculosis mortality. The 2 nurses in the county traveled over 17,000 miles and made a total of 3,000 home visits. During 1929 the first deaths in 4 years in the county from diphtheria occurred, there being 5 cases with 2 deaths. In 1929, 649 school children were immunized against diphtheria. During the summer, 456 children in the county and 125 others in Troy city attended preschool conferences. The estimated population of the county is 26,699.

Jamaica—The government of Jamaica, in the 1929 report, calls attention to the increasing interest in public health matters as shown by Parochial Boards and by the general public, and attributes much success to the work of

the Bureau of Health Education. A law has recently been passed enabling the government to give financial assistance to public bodies desiring to establish or improve public water supplies. If the plan is approved by the Colonial Office in England, during 1930 the report of the Medical Commission will become effective, providing for the employment of a full-time health officer in each parish; to be selected, paid, and supervised by the Central Board of Health.

The present coöperative health work consists of units for the control of hookworm through sanitation and treatment, health education, school hygiene, school for sanitary inspectors, malaria control, tuberculosis survey and clinic study, and parochial health departments. The work of each of these units is discussed in detail. During the year 1927–1928, there was expended by the Central and Local Boards of Health 83,941 pounds as compared with an expenditure of 45,121 pounds during 1922–1923.

Indiana—The 1929 report of the Division of Infant and Child Hygiene traces the history and activities of the Division since 1922. "When one considers that 77,592 children have had a thorough health examination in Indiana Child Hygiene Conferences and that each child usually has 2 parents, 4 grandparents and many other relatives who are interested, one may safely multiply the number of children by 4 to estimate the number who have received instruction in child care and training, with a child in whom they are interested as an object lesson."

Courses of study have been presented in classes for women, arranged in coöperation with physicians and nurses. Audiences totaling 606,364 have viewed health films and listened to health talks since this work was organized. Over a million pamphlets have been distributed.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Physical Defects and Occupation—Summarizing the findings of a study of adult health as revealed in 100,000 records of health examinations which are reported in detail elsewhere. Interesting graphs, skillfully done.

ANON. Physical Impairments among Males of Different Occupational Classes. *Quarterly Bull. (Milbank Memorial Fund)*, 8, 3: 58 (July), 1930.

Measles Anti-Sera—Convalescent serum proved a better prophylactic agent than adult whole blood. But as whole blood is much more readily available and is of value in attenuating measles, it is the most practical method. Immune goat serum (Tunncliffe) failed to protect.

BARENBERG, L. H., *et al.* Measles Prophylaxis. *J. A. M. A.*, 95, 1: 4 (July 5), 1930.

Diphtheria After-Effects—The conclusion of this paper, "Diphtheria in childhood appears to be an etiological factor in the development of heart-block in later years," is significant in view of the fact that the former teaching that "diphtheria injures the heart" seemed to be in the process of being successfully exploded.

BUTLER, S., and LEVINE, S. A. Diphtheria as a Cause of Late Heart-Block. *Am. Heart J.*, 5, 5: 592 (June), 1930.

Schoolroom Ventilation and Health—Contribution No. 2 of the New York Commission concludes that differences in schoolroom temperature fail to affect the prevalence of respiratory diseases, thus differing from earlier reports. This final report of the 3-year study will be read with interest in view of the rather heated resolutions once

adopted by the A. P. H. A. at its 1925 Annual Meeting.

COLE, R., *et al.* A Study of Ventilation and Respiratory Illness in Syracuse Schools; with an Analysis of Factors Affecting Criteria Used. *Am. J. Hyg.*, 12, 1: 196 (July), 1930.

More Schoolroom Ventilation—The engineer's version of the open window-plenum system controversy, presented by an able committee. Health officials will want to hear the other side of the story, whatever their opinions may be.

DUFFIELD, T. J. The Principles of School Ventilation. *Aerologist*, 6, 4: 5 (Apr.), 1930.

How Do You Sleep?—Have you had, or have you given advice about sleeping in this or that position? Here is presented a record of the gyrations a normal sleeper goes through in the course of an 8-hour nap. A perfect example of scientific demonstration that demolishes a dozen unscientific theories.

JOHNSON, H. M., *et al.* In What Position Do Healthy People Sleep? *J. A. M. A.*, 91, 26: 2038 (June 28), 1930.

Seasonal Fluctuations of Infections—Carefully collected Danish morbidity statistics furnish the author with excellent material for a broad consideration of the causes of seasonal variations of infectious diseases. A paper with which every epidemiologist ought to be familiar.

MADSEN, T. J. M. The Seasonal Variation of Infectious Diseases. *Pub. Health*, 43, 10: 309 (July), 1930.

Viewing-with-Alarm—The President of the A. M. A. portrays the dark side of German and English state medical service, couples the Sheppard-

Towner with the Volstead Act and labels them "paternalistic monstrosities" and finally wonders "what proportion of the appalling increase in the number of mental patients in our country at the present time may be traced to too much paternalism applied through the various correlated mental hygiene agencies."

MORGAN, W. G. The Medical Profession and the Paternalistic Tendencies of the Times. *J. A. M. A.*, 94, 26: 2035 (June 28), 1930.

Early Diagnosis of Whooping Cough—The cough plate method for early diagnosis of pertussis is discussed. A potato agar is the medium.

SAUER, L. W., and HAMBRECHT, L. Whooping Cough. *J. A. M. A.*, 95, 4: 263 (July 26), 1930.

Teaching Nutrition—A résumé of the work of Detroit Health Department's Nutrition Division, and a plan for the future. An important project, interestingly summarized.

SIMPSON, D. S. Activities of the Nutrition Division. *City Health (Detroit)*, 16, 4: 3 (May and June), 1930.

Air Conditioning in Hospitals—Four years' experience in the air conditioning of nurseries for premature infants resulted in a lowering of the diarrhea incidence and mortality rates.

YAGLOU, C. P., *et al.* Application of Air Conditioning to Premature Nurseries in Hospitals. *Am. Soc. Heat. & Vent. Eng. J.*, 2, 7: 605 (July), 1930.

Maternal Mortality Causes—Half the women dying in childbirth in Michi-

gan never consulted a physician until just prior to death. Other preventable causes of maternal death are recorded, and the preventive measures are considered.

SMITH, L. R. Maternal Mortality. *Public Health (Mich. Dept. of Health)*, 13, 7: 148 (July), 1930.

Mississippi's Rural Health Work—Health problems are local and require local machinery, promoted and assisted by the state, to insure adequate health protection. These are, in essence, the conclusions from Mississippi's experience in rural health administration.

UNDERWOOD, F. J., and APPLEWHITE, C. C. Whole Time County Health Work in Mississippi. *Southern M. J.*, 23, 6: 505 (June), 1930.

Tuberculosis Case Finding—This report of the sixth year of work of the Chadwick Clinics (Mass.) deals with the problem of the incipient and pre-tuberculous case after he is found.

WAKEFIELD, P. Children's Tuberculosis Program in Massachusetts. *New Eng. J. Med.*, 203, 4: 168 (July 24), 1930.

Whither Propaganda—The mental hygienist and the cancer prevention propagandist come in for some sound berating. Some of the metaphors are mixed and the style is perhaps unduly vigorous, but health educators will be benefitted by reading this paper.

WECHSLER, I. S. The Legend of the Prevention of Mental Diseases. *J. A. M. A.*, 95, 1: 24 (July 5), 1930.

NEWS FROM THE FIELD

EIGHTH TEXAS SANITARIANS SHORT SCHOOL

UNDER the auspices of the Texas Association of Sanitarians, with the Texas State Department of Health, the City of Amarillo, and the Amarillo Chamber of Commerce, was held the Eighth Sanitarians Short School, August 26-28, with headquarters at the Hotel Herring.

CAPPER AWARD TO DR. BABCOCK

DR. Stephen Moulton Babcock, emeritus professor of agriculture and chemistry at the University of Wisconsin, the inventor in 1890 of the Babcock milk test which revolutionized the dairy industry, is to receive the Capper award of \$5,000 and a gold medal at the annual meeting of the American Country Life Association, to be held at the University of Wisconsin from October 7 to 10.—*Science*, Aug. 1, 1930.

RECREATION PARKS

THE National Recreation Association announces, as the result of a study of county parks just published, that the number of counties providing parks has doubled since 1926, 66 counties in 19 states now having reserved a total of 46,564 acres for their people's play and outdoor life. The first county park in America was set aside by Essex County, N. J., in 1895.

Michigan leads with 12 counties making park provision, and California is second with 10.

Preserving for future generations places of unusual scenic and historic interest has been one of the most valuable effects of the movement, according to the study. Without county action, such places would have been utilized for

commercial or residential uses. The transformation of polluted streams, valleys, mosquito infested marshes, and dumping grounds into attractive landscaped areas has had a striking and beneficial effect in many counties.—*County Parks*, National Recreation Association, 315 Fourth Ave., New York, N. Y.

BOVINE T. B. DECLINES

A STEADY decline in the prevalence of bovine tuberculosis in the United States has taken place in the last few years as a result of the coöperative campaign to eradicate the infection. The average infection among cattle, for the entire country, is now 1.7 per cent, whereas in 1922 it was 4 per cent.

On May 1, 1930, there were 946 counties officially designated as "modified accredited areas," also 42 towns in Vermont, indicating that these areas are practically free from bovine tuberculosis.

UNIVERSITY OF SOUTHERN CALIFORNIA

THE new Physical Education Building of the University of Southern California will be ready for use during the 1930 fall semester, which opens on September 15, according to Professor William Ralph LaPorte, chairman of the department of physical education. The structure covers a half-block, and includes many unique features.

RESEARCH FELLOWSHIPS

THE National Tuberculosis Association announces the appointment of three research fellows for the academic year 1930-1931. The successful candidates were selected from a large number applying from all parts of the country

The three to whom the awards were made are: Alvin E. Belden, M.D., Lancaster, Pa.; William F. Lawrence, Portsmouth, Va.; and Edna E. Nicholson, A.B., Ann Arbor, Mich.

COFFEE SELDOM FOUND TO VIOLATE FOOD LAW

DOES your breakfast coffee have a smooth rich flavor with just a slight sharpness to give it refreshing zest?

It should have, and most of the 1,400,000,000 pounds imported annually into the United States do have, says the U. S. Department of Agriculture. Inspectors of the Food and Drug Administration seldom find coffee to be in violation of the pure food law. Adulterated coffee is immediately seized to prevent sale to a public which wants and has a right to expect its coffee to be pure.

PINK BOLLWORM STOPPED

SEVERAL pink bollworms stowed away in a small package of cottonseed sent by mail from India met a timely death recently when the package was examined by a United States plant quarantine inspector at Atlanta, Ga. The inspector immediately ordered the contraband package burned, thus preventing a potential invasion by this pest. The pink bollworm is a destructive pest of cotton, regarded by entomologists as at least in the same class with the boll weevil.

DICK PATENT HELD VALID BY FEDERAL COURT

IN a somewhat lengthy and involved opinion handed down on June 9, 1930, in a case brought by George F. Dick and Gladys Henry Dick against the Lederle Antitoxin Laboratories, the U. S. District Court for the Southern District of New York held that the Dick patent on scarlet fever toxin and anti-

toxin and the processes for their manufacture granted in 1925 is valid and had been infringed by the defendant. A perpetual injunction enjoining the Lederle Antitoxin Laboratories from using the process or selling the product was issued, and an accounting of sales already made was ordered.

In deciding this case after five weeks' presentation of evidence, the Court held that the methods described in the patent are an invention and not a mere discovery, that it is useful, that there had been no anticipation of the process by others, that the Dochez patent was different, that the Dick patent had been infringed by the defendant's toxins and antitoxins, and that the claims in the Dick patent must be sustained. "The testimony is overwhelming and convincing," declared the Court, "that until we got the Dick test the world had no way at all to determine susceptibility to scarlet fever with precise certainty and definiteness."

This decision is not, of course, final, as an appeal can be taken to the Circuit Court of Appeals. If it is not, or if this decision is sustained, the use of a scientific method of universal benefit to humanity remains in the control of these two individuals until the period of the patent expires.

SANITARY SUPERVISION OF CANNERIES

A. L. SULLIVAN, Chief of the Bureau of Food and Drugs of the Maryland State Department of Health, at the request of a committee of representative canners, has directed the attention of the canners throughout the state to the requirements concerning the industry. He recommends that each canner assign a sufficient number of persons to be responsible for the general sanitation of the plant; to see that the place is cleaned up twice a day; and to supervise the living quarters of the workers.

Number 10

The Training of Health Officers*

J. C. GEIGER, M. D., F. A. P. H. A.

Professor of Epidemiology, The George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

PREVENTIVE medicine is increasingly dominating the thoughts of not only the medical profession but the general public. National health is truly national wealth and full recognition of this will add to the happiness of the nation. Today, the major diseases of yesterday are and can be dimmed to practical insignificance by modern methods of sanitation and immunization. Protection against such diseases as typhoid, smallpox and diphtheria can be obtained and attained without effort or danger.

Unfortunately, the public health movement does not always go forward smoothly and perhaps sometimes intelligently. Any calamity begets reforms. Health is a positive condition but many times its opportunities are overlooked. To be sure, parsimonious activities are first practised in the health department but thrift in expenditures for health matters must be wisely guided. It is perfectly true that half of the general public is not aware of how the other half lives. Ignorance in accepted health principles is inexcusable; therefore, the responsibility of health departments in communicating knowledge regarding such principles is obvious. This educational procedure must be based on facts, and such facts are usually obtained from painstaking research in universities by philanthropic foundations, health departments, and governmental agencies.

As a result of research, one can now appreciate and evaluate the effect of sunlight and proper ventilation on disease, and last but not least, the effect of food. This type of knowledge is invaluable since

* Read before the Western Branch, American Public Health Association, at the First Annual Meeting at Salt Lake City, Utah, June 13, 1930.

cities are growing larger; transportation facilities are increasing and sometimes more difficult; and the economies of better living conditions are not so easily understood and handled. The scriptures have well said, "As ye go, teach." Life in America is undoubtedly more pleasant and the passing years have seen it markedly prolonged. A vexing problem, however, exists. Health work is primary and fundamentally attached to medicine in all of its many branches. Therefore, the health officer must receive or obtain the broadest training, and today his is the specialty of medicine most unappreciated by organized medicine itself.

Political machinations and interference with the position of health officers frequently lead to changes in the personnel and sometimes in the whole department when the complexion of the political parties changes. That to be a good health officer one must be a graduate physician is certainly not an infallible rule. Some of our excellent health officers and teachers of public health are not physicians, yet this handicap must be fully admitted when put to actual practice by the necessary contact with medicine. Obviously, the trained medical health officer is of paramount importance, but this fact is not taken into consideration by politicians. The history of such political upheavals, however, should constantly guard us against the appointment of the untrained; for the general public generally suffers from an increased mortality or morbidity disease rate. The politician, thick-skinned, hard-boiled, smooth, suave, or of whatever type, listens only to votes and the active, friendless, efficient and scientific health officer is more of a vote liability than an asset.

Until some permanence of office is assured, either politically or by the intervention of organized medicine, trained health officers will be floaters on the sea of politics and usually jetsam and flotsam of the medical profession. This unfortunate fact probably accounts as no other for the unwillingness of the young physician to seek further training in public health; and the lack of effort in many medical schools to permeate their entire curriculum with the spirit and methods of preventive medicine and public health procedures may account in part, at least, for this abortive and somnolent regard manifested by the medical students today.

THE PROBLEM OF THE HEALTH OFFICER

There can be no question that a career in public health does not today offer sufficient attraction, financial or otherwise, to our students or medical practitioners. Perhaps, the passing by Congress of the recent reorganization bill of the U. S. Public Health Service, may

show a trend to better things to be expected elsewhere. Certainly, the need for competent officials is greater than the demand. Three things deter good men: lack of knowledge, inadequacy of compensation, and uncertainty of tenure.

Lack of knowledge as to character of work, and the technical and personal qualifications necessary is bound to react unfavorably on the service performed. The curriculum of schools, medical or otherwise, that give public health courses should be presided over or guided by an experienced and successful health official. Only such an individual is capable of pointing out the advantages and disadvantages of a public health career when compared with private practice. Too often the teacher has the technical requirements but not the practical touch. The student must have it stressed that tactlessness, arrogance, and political subservience are the main pitfalls, with the inability to achieve results along known and safe lines.

Of extraordinary importance is the endorsement of the medical profession of new work to be attempted and the policy of sound financial economy and expenditure. Whenever physicians become interested in public health work, it will be of benefit to the public and to the profession. This kind of endeavor is not by any means a conspiracy against the profession for they gain more than they give.

Political judgment in putting over work is often regarded as a criterion of the successful administrator. Knowledge of disease conditions at home and abroad must remain in the foreground, for the modern health department must teach by the written and spoken word, by exhibits, pamphlets and other propaganda, in order that the seeds of sanitation be planted in the soil of the larger audience.

Two of the modern weapons of health work are bacteriology and epidemiology. Many of our older and sometimes successful health officials regard them as synonymous. As a matter of fact, Lemology or Lemography, meaning the sum of human knowledge as to pestilence, was known long before the science of bacteriology came into existence. The application of these subjects to problems is many times neglected or mishandled by the ordinary health department. Another problem that is often neglected is that of midwifery. It is no vapid utterance that this not unimportant cause of infant and maternal mortality is usually 40 per cent incompetent and uninformed. Furthermore, the use of knowledge by the health official will combat cults, for they appeal, like medicine of ancient days, to the mysterious, the undoable and the unknowable, while modern medicine appeals to the intelligence.

The health official should realize that public health and hygiene

are not entirely medical problems but have economic, sociologic and psychologic aspects.

There can be no doubt that the efficient full-time official is not adequately compensated. Unfortunately, it must be equally realized that as the years pass such an official may become less able to meet the competition of private practice, and once eliminated, the staging of a comeback is exceedingly difficult. Medical men in part-time health department work often complain that such contacts are harmful in establishing practice and good material hesitates to enter even this field. We lose, therefore, many of our best men who can ill afford to enter the domain of public health. The advent of Civil Service regulations in health departments by no means solves this problem for it may act both ways, protect the incompetent, impede progressive thought and work by smug complacency, and be used as a lethal weapon by politically wrong minded boards of control. Rightfully and judiciously applied it offers great possibilities in continued good service by capable men.

This brings up the uncertainty of tenure of office, which acts as a deterrent to entering public health. Many health officials bear in their subconscious minds the sad and repeated history that satisfactory performance of duties is no criterion, and that for political reasons they may be thrown out of office. The adult American intelligence en masse approaches closely that of the grammar school and apparently is woefully lacking in separating political humbug from party policies. There should not be any political interference in health department work and conversely, no partisan decisions by health officials. Well conducted health work very often constitutes an asset that political parties cannot afford to neglect.

The health official must realize no matter how thorough his training and how broad his knowledge, that he should surround himself with the best of assistants, equally well trained, equally well paid, and equally sharing in the published data. The establishment of advisory councils drawn from universities, medical societies and social agencies, appears to be not only necessary but fundamental. Unfortunately, this measure is often regarded with suspicion by politically minded and narrow visioned health officials. Many wholly untrained persons occupy front line positions in public health in the United States, and the trained must depend on a secured solidarity of public opinion based on the education of the community and the medical profession to the necessity of having trained health workers. The politician is not always unwise and the health officer who cannot be an honest, incorrupt one may prove impractical in the final analysis even to politicians.

TEACHING OF PUBLIC HEALTH

The teaching of public health is an argumentative point as to methods of procedure. The advocate of initial training in schools of public health followed by some practical field work either in state, county or city departments apparently has the best of the argument at present. Those who advocate practical experience, preliminary to a collegiate course in public health have been frowned upon because of time limits, financial vicissitudes, and the unwillingness of health departments to recognize this valuable asset of offering such training to their qualified men on leaves of absence.

There has also developed the so-called "in-bred" schools in departments themselves in which new and old employees are trained. This type of training is undoubtedly invaluable for new employees as to certain technical procedures within the department, but its limitations are many when compared to collegiate work in good schools of public health. Perhaps, of greatest importance is the possibility of establishing short courses in these or in medical schools by their own and invited staffs for the training of health officials and the review of pertinent subjects.

It is the modern trend of medical schools to provide instruction along lines of preventive medicine especially in vital statistics, laboratory methods, epidemiology, water and sewage, mental, dental and industrial hygiene, public health administration and education. Unfortunately a usually crowded curriculum perforce must restrict this manner of teaching to lectures. It has become recognized, however, that field trips are necessary to round out such a program. Naturally, such a course cannot be given in its entirety by one individual, as it combines collective and selective knowledge possessed by none or few. Furthermore, the existing facilities of the medical school should be coördinated with those of a well organized health department, be it state, county or city, so that didactic work can be combined with practical training to the benefit of all concerned.

At the Annual Meeting of the American Public Health Association in New Orleans in 1919, a committee of 16, of which the writer was a member, was appointed to consider the subject of standardization of public health training. This committee was cognizant of and in cordial agreement with the expressed idea that the tasks of public health administration require a standardized professional training which would adequately prepare for positions in the public health field and that the possession of such training should be indicated by accredited degrees.

In 1919, Yale University held a conference with representatives of

Johns Hopkins, the Massachusetts Institute of Technology, Harvard, New York University, and the University of Pennsylvania. The committee as well as the Yale Conference came to certain conclusions, practically identical. One of the defects stressed of the system then in vogue was that certain institutions gave not only the certificate in public health but even the doctorate of public health for a course of a few weeks, while others required several years. The committee's opinion was that the first degree should be a Certificate in Public Health, or a Master of Science in Public Health, to be granted for 1 or 2 years of postgraduate work along suitable lines, and the highest degree should be Doctor of Public Health to be granted for not less than 2 years of work in academic residence. Students in the latter course must have the Bachelor or Medical degree, or have satisfactorily completed 2 years in an approved medical school which requires 2 years of college or pre-medical work. The Yale Conference, however, unanimously adopted the resolution that the Doctor of Public Health degree should be for graduates of medicine, and normally awarded after 2 years of work under academic direction, of which, 1 year at least be in residence.

The committee's survey showed 21 schools in the United States and Canada that conferred various degrees in public health, 2 of which allotted them in 36 hours and 6 weeks respectively. Ten schools gave both a certificate and a Doctor's degree in public health. The committee of 16 was replaced by one of 5 members, and in a survey reported October, 1923, the schools conferring degrees in public health in the United States and Canada were reduced to 13 in 1922, but increased to 18 in 1923, 19 in 1924, 21 in 1925, 18 in 1926, and 18 in 1927. These graduated or granted degrees to 66 in 1921, 87 in 1922, 92 in 1923, 98 in 1924, 97 in 1925, 104 in 1926, and 98 in 1927. The University of California in these years reported the conferring of 38 degrees, Yale University 58, Johns Hopkins 267, Harvard 81, Massachusetts Institute of Technology 61, Laval University 10, University of Pennsylvania 17, University of Toronto 30, McGill University 9, University of Iowa 6, New York University 8, and various other universities 1 or 2 degrees each.

About this time short courses were made available in 11 universities and 8 state departments of health. Apparently, in universities the consensus of opinion is that the fundamental subjects to be taught are sanitary and diagnostic bacteriology, sanitary chemistry and biology, vital statistics, theoretical and applied hygiene, sanitary law and legislation, epidemiology, preventive medicine, sanitary engineering and public health administration. To increase the students' perspec-

tive, sufficient postgraduate study in a qualified health department seems necessary. The short courses, however, should cover special subjects by specialists in their fields in the various universities; studies in subjects in state, city or county departments of health; and perhaps correspondence courses arranged in coöperation with both the department of health and the university, and demonstrations in the field.

DISCUSSION

We rightfully revere Louis Pasteur, the real founder of preventive medicine. The revolutionizing of medicine so ably begun by a chemist, was given great impetus by Tyndall, a physicist, and Robert Koch, a bacteriologist. Bacteriology has in turn, revolutionized our isolation and quarantine procedures particularly as to the recognition of the healthy carrier. There is no doubt that Theobald Smith focused attention on the importance of transmission of disease by insects. Biggs really modernized public health practice in the United States.

Scientific medicine and public health are not yet closed books, but to many health officers thinking is yet a painful process. Problems are constantly coming up and awaiting solution. One of these is that of trained personnel in public health. Health departments may acquire funds and secure legal power, but expert knowledge, enthusiasm and personal and political integrity are needed in order to obtain maximum results. The mediocre and untrained health officer will always be with us. Nevertheless, the most deeply important phase of the matter and of the future is to make serviceable the sympathetic and active efforts of organized medicine.

The full-time health official has no petty position—his duties are not dribbling matters and his remuneration should be adequate. Many universities have foreseen the need of such training and there is no lack of facilities. The recruiting of the medical profession is, however, sadly lacking and most needed. The newer phases of public health must perforce receive the application of medical knowledge to the detection and prevention of disease. Jordan, in 1922, showed that out of 461 students replying to a questionnaire, 358 had never even considered entering public health work. Moreover, the replies indicated prejudice against this type of work.

A questionnaire was recently submitted to the junior and senior classes of the medical school of the University of California, and apparently there has been no change in opinion. For instance, the answer to the question "Do you intend to take up public health as a career?" was unanimously in the negative, and it was invariably stated that politics and insufficient remuneration guided the decision.

In fact, one answer carried this cryptic statement: "The health officer is too frequently a glorified policeman; and the position too thankless and too poorly paid." One redeeming feature of these answers, however, was the obviously inherent desire to assist the health officer in reporting disease and work in harmony with any program for the prevention of disease. Many students confessed to knowing very little of the health organization in their home city, county or state and when they did show some familiarity, it was the hackneyed pious type of phrase—too much politics.

Presumably, the health officers of the Pacific Coast and slope are not sufficiently well acquainted with medical students—at least, at the University of California—to impress them with their objectives or their methods, nor are their instructors quite able to interest them or remedy this condition without active contact with health departments. In this connection, a health department which has one of the best balanced organizations and an unsurpassed record for achievement, research and activity—that of Detroit—makes this interesting assertion:

The health department has several assistants under training at all times and makes a special point of taking young and promising students from such schools as the University of Michigan, Massachusetts Institute of Technology, and Johns Hopkins School of Public Health. There are four such men on our staff at present working for higher degrees in public health. In addition to this, all Bureau and Division heads are well trained men who are continually availing themselves of opportunities to improve themselves in their specialized field. Moreover, we are great believers in well trained executives and have on our staff men of national reputation in communicable disease work, laboratory, tuberculosis, health administration and epidemiology, venereal disease and sanitary engineering. Likewise, this department coöperates in teaching preventive medicine and public health at the one class "A" medical school. All senior students have a course in communicable diseases, tuberculosis, and maternity service at the Herman Kiefer Hospital. Internes have these same services.

Lectures on preventive medicine and field demonstrations are given to third and fourth year medical students by members of the staff of the health department. Senior students are in daily attendance at our venereal disease and tuberculosis clinics where they receive personal instructions. The staff also gives lectures in public health administration at the University of Michigan in Ann Arbor both during the school year and in special summer institutes.

The Department of Health in Chicago, at least in years past, covered the same activities but for 4 class "A" medical schools. The future of such work is naturally problematical, but such a department is wholly fulfilling its obligation to preventive medicine. One may go so far as to build around the medical school an active ideal health department unit with its own personnel where practical experience may be given students, nurses, etc. This type of unit, however, can only

be established when the health department has far-seeing executives who can appreciate the value of such mutual contact.

Of more than passing interest is the fact that hospital nurses should come to graduation with a practical knowledge of bacteriology, epidemiology, and public health. Too often their instructors are technicians or members of the hospital staff years removed from the subject, or staff nurses selected because of their inadaptability for other duties. It is perfectly true that prescribed courses are mentioned in the curriculum for hospital nurses but it is not infrequent that the course in bacteriology, at least, is given without the student obtaining actual laboratory experience. It is likewise true that hospital nurses are not intended to be bacteriologists but their varied duties are such that sterile technic at the bedside and in the operating room is dependent upon existing bacteriologic flora and a workable knowledge of the reasons for possible contamination and the contaminants is necessary. Just as necessary are the fundamentals of the epidemiology and public health measures to be used to combat disease. The nurse is quite frequently the confidant and companion of the patient and the understanding of questions with their proper answers is equally as important as is sympathy and bedside care. Superintendents of hospitals should carefully scrutinize such instruction in order that the graduate nurse will have adequate familiarity with laboratory technic and public health procedures.

It can be generally admitted that practically every disease affecting the human being is susceptible to some measure of control. The health officer of the future must assume the responsibility of guiding the attack on these. Control does not mean the application of police power, the making and passing of new ordinances, or presuming that ordinary quarantine is continuously effective. The medical profession should have intelligent and serious regard for such matters and give their active coöperation. Likewise, the medical school must realize that in the undergraduate curriculum, a place of importance must be given to preventive medicine. The time of placement is of equal importance, and perhaps such teaching should be concentrated on the fourth year. As an offshoot of the year when bacteriology is usually taught (second year), special field problems could be offered with possibly apprentice work in health departments. Moreover, all teachers of medicine should conform their courses with the newer accepted ideas that the duty of the physician is to promote health and prevent disease.

The health officer is perfectly well aware that 30 per cent or more of confinements occur without medical attendance. As a result the

Home Pasteurization of Milk

LLOYD ARNOLD, M. D., AND C. J. GUSTAFSON

*Research Laboratories, State Department of Public Health and College of Medicine,
University of Illinois, Chicago, Ill.*

THE advantages of pasteurized milk need not be dwelt upon in this JOURNAL. Our purpose is to report experiments upon the use of vacuum and insulated heat retaining bottles to pasteurize milk in small quantities suitable for home use. This is a part of a program of the Illinois State Department of Public Health to reduce infant mortality in communities too small to enjoy the benefits of commercially pasteurized milk.

Illinois has an approximate population of 4 million people living outside of the city of Chicago, at least 70 per cent of which uses raw milk.

A recording thermometer was used for these experiments. The readings were checked with certified mercury thermometers. Water, milk and other fluids were heated to various temperatures and placed in vacuum vessels of various sizes and types, and the heat retaining efficiency of each vessel graphically recorded on a circular ruled paper by a moving writing point, moved by a time clock. The results are presented in tables, calculated from averages from the time and temperature graphs. The temperatures varied from 100° to 200° F. We are only concerned in this article with those temperatures that are of practical use in the pasteurization of milk for human consumption.

Milk was heated in an open vessel to a given temperature, then placed in a vacuum bottle and the heat retaining efficiency of the closed vacuum vessel determined. Such a vessel can act as an incubator under certain conditions. The object of our experiments was to find a vessel of the proper size that would retain the heat of the milk for the longest period before it served as an incubator for its contents.

This part of the problem divided itself into 3 factors: (1) duration of the holding or pasteurization temperature; (2) length of time that the milk would be warm but wholesome; (3) time when the vessel cooled to a degree that would incubate its contents.

When the continuous recording thermometer is used over a long

* *B. Abortus Porcine.*

Table VI shows that 115° F. is the lowest temperature at which milk can be held in vacuum bottles before bacterial multiplication begins.

We thought it advisable to use some other indicator for temperatures than the mercury thermometer for the home pasteurization, since initial cost and probable breakage would not aid in the widespread use of this procedure. We have developed two indicators that will replace the mercury thermometer and can be used by the mother in the kitchen. Palmitic acid has a melting point of 145° F. Sealed in an ampule it changes from an opaque to a water clear color when 145° F. is reached. Thin glass tubing 11 mm. in diameter has been made into ampules approximately 45 mm. long, into each of which 400 mg. of palmitic acid was placed, then sealed.

An ampule is dropped into the milk in a pan on the stove. During heating the milk is constantly stirred with a clean spoon. When the floating ampule becomes colorless the temperature has reached 145° F. In our experiments the actual temperature of the milk is seldom less than 147°, and at times 149° F. This is because of exposure of part of the ampule to the air and the poor conductivity of the glass.

140° and 115° F. Table IV gives this in condensed form for the 6 vessels used. These results are averages of 100 experiments outlined in Table I.

It will be seen from Tables III and IV that the 1 quart vacuum bottle is a very efficient instrument for pasteurizing milk. The 2 quart vessel is insulated and the cost is out of proportion to its size when compared with the 1 quart vacuum bottle. The $\frac{1}{2}$ pint and the pint vacuum bottles, and the gallon insulated jug should not be used for home pasteurization for two reasons: (1) the holding time between 145° and 140° F. is too short, and (2) the length of time between 140° and 115° F. is too short for safety.

TABLE IV

LENGTH OF TIME THE MILK WAS SUBJECTED TO PASTEURIZING TEMPERATURES (145° TO 140° F.).
LENGTH OF TIME THE MILK WAS HELD AT TEMPERATURES BELOW PASTEURIZATION POINT, BUT
BEFORE BACTERIAL MULTIPLICATION BEGAN

	$\frac{1}{2}$	Pint 1	$1\frac{1}{2}$	1	Quart 2	4
Length of time 145° to 140° F.	8 min.	45 min.	1 hr. 5 min.	$1\frac{1}{2}$ hrs.	1 hr.	35 min.
Length of time 140° to 115° F.	1 hr. 8 min.	5 hrs. 40 min.	6 hrs. 55 min.	$9\frac{1}{2}$ hrs.	12 hrs.	8 hrs. 20 min.

Various bacteria have been added to the milk to test the efficiency of this method of pasteurization. Most of these experiments have been carried out with the quart vacuum bottles. The bacteria were added to 2 quarts of milk, heated to the temperatures indicated, and put into two 1 quart vacuum bottles—1 c.c. samples were removed after 30, 35, 40 and 45 minutes. The results are given in Table V. Each organism was used for 3 experiments and each experiment was run in duplicate; hence, the bacterial counts on each line in Table V represent an average of 6 counts.

We found that the porcine strain of the *B. abortus* was the most resistant of any of the bacteria tested. We have not used the *B. tuberculosis* in these experiments, as there are many observations recorded upon its thermal death point. If the milk is held between 145° and 140° F. for 1 hour there is a wide margin of safety and it will be free of pathogenic bacteria. Table VI is similar to Table V, except that we used the $\frac{1}{2}$ pint vacuum bottle. Tables III and IV show the short period that the milk will be held at pasteurizing temperatures in this small vessel. This accounts for the inefficiency of the $\frac{1}{2}$ pint vacuum bottle (Table VI) as compared to the quart bottle (Table V) for pasteurization purposes.

and boil for 10 minutes. Pour water out of pan carefully, leaving the clean stopper in the empty pan.

3. Clean a pan well and pour 1 quart of fresh clean milk into it. Milk should be free from dirt and less than 12 hours from the cow.

4. Drop indicator No. 1 into the milk. Place pan on the heated stove and bring temperature of milk up rather slowly, stirring constantly with a clean spoon.

5. When the indicator No. 1 becomes transparent, the temperature of the milk has reached 145° F. Remove milk from the stove. Take out indicator No. 1 with spoon and put on table.

6. Pour the hot water out of the vacuum bottle.

7. Pour the hot milk into the heated vacuum bottle. Stopper the bottle.

8. Set the vacuum bottle in a warm cupboard in the kitchen and leave it there until the milk is to be used.

9. Do not use this milk until it has stood in the vacuum bottle for at least 1 hour.

10. Use the indicator No. 2 (with glass stem) to determine whether the milk in the vacuum bottle is warmer than 115° F. Hold the end of the glass tube in the hand and put the opaque bulb down into the milk in the vacuum bottle. Hold it in the milk for 2 to 4 minutes. If it is above 115° F. the bulb will clear. If below it will be opaque.

11. If the milk is at a temperature above 115° F., pour out enough to make a feeding. Replace the vacuum bottle and the remainder of the milk in the cupboard.

12. When the milk in the vacuum bottle becomes cooler than 115°, it should be discarded.

The thermal death points recorded in this experiment have been determined by using the vacuum and insulated bottles. Our problem was to determine the thermal death point of bacteria using the method we have suggested for pasteurizing milk in the home.

One Murder in Year Norway's 1928 Record

UNITED States cities where the murder rate has shown a tendency to jump in recent years might profit by studying conditions in Norway, according to figures presented recently before the Commons Committee on Capital Punishment, which show that Norway had only one murder in 1928.

And the tendency is decreasing, due to abolition of the penalty of capital punishment, M. Kristian Hannson, secretary of the Norwegian prison commission, told the committee.

Growth of culture, a higher standard of living, and better police organization were given by Mr. Hannson as explaining the decrease in crime.

Punishment for premeditated murder in Norway is from 6 to 20 years. Good conduct men can be released after serving two-thirds of their sentence.

TABLE VI

BACTERIA ADDED TO MILK, HEATED TO TEMPERATURES INDICATED AND PUT IN $\frac{1}{2}$ PINT VACUUM BOTTLE. BACTERIAL COUNTS MADE UPON 1 C.C. SAMPLES AT INTERVALS INDICATED

TABLE VII

BACTERIAL COUNTS OF 1 QUART SAMPLE OF FRESH MILK IMMEDIATELY AFTER HEATING AND POURING IN VACUUM BOTTLE AND AFTER TIME INTERVALS NOTED. TEMPERATURES TAKEN AT TIME BACTERIAL COUNTS ARE INDICATED

Hours	At start	3½	6½	9	12	16	21	25	28
Temperature	146.75° F.	140	135	130	125	120	115	110	108
Colonies	300,000	0	0	0	0	300	1,800	7,000	300,000

Inasmuch as the cream line is of no importance in this method we have considered the added temperature of 2 to 4° above 145° advantageous. The second indicator is menthol. A glass tube $4\frac{1}{2}$ mm. in diameter, of approximately 8" in length, is blown out at one end into a bulb, into which menthol is placed and the open end of the tube sealed. Menthol changes from an opaque substance to a clear fluid at 108° F. This indicator is for the purpose of determining if the vacuum bottle has become an incubator. When it is suspended in the milk and remains opaque the milk is not to be used for human consumption. If it changes to a clear fluid the milk is still safe for use. The equipment necessary to carry out this method of pasteurization will cost less than \$3.00. We give the detailed instructions as to the technical procedure.

EQUIPMENT

1. Pan of more than 1 quart capacity with side lip to facilitate pouring of milk from pan into bottle
2. Vacuum bottle of 1 quart capacity
3. Temperature indicator (No. 1) for pasteurization in sausage shaped glass tube
4. Temperature indicator (No. 2) for cooled milk—a long glass tube with bulb on end

PASTEURIZATION TECHNIC

1. Clean out vacuum bottle with hot soap water several times. Rinse well with water about 160° F., fill bottle with this water and let stand.
2. Wash the stopper of the vacuum bottle well, put it in a small pan of water

projects have been developed along the California-Arizona line with a total irrigable area of 867,000 acres, about three-fifths of which is in Imperial Valley with a population of over 60,000, about half of which is rural. The reclamation of this land has not been easily nor cheaply achieved; constant vigilance has been necessary to prevent a repetition of the break in the levees which occurred in 1905 when the river for 18 months flowed into the Salton Sea. Silting has raised the river bed about one foot per year until it now flows confined by levees on a silt ridge 300 feet above the lowest point of the Valley. Overtopping of levees is an annual menace with each year adding to the danger.

The river has been observed and studied since the close of the Civil War, but has been intensively surveyed for the last 10 years. The present plan for regulation by a dam at Black Canyon has a five-fold object: (1) flood control for the lower basin, (2) desilting of the water, (3) conservation for irrigation use, (4) conservation for domestic use, and (5) development of hydro-power. This discussion is concerned primarily with the use of the water for domestic purposes which may be construed to include industrial purposes.

In the lower basin the present users of the water for domestic purposes include the cities of Needles and Yuma, also 11 communities of the Imperial Valley which take their supplies from the irrigation canals. Of the latter, El Centro for purification uses long subsidence and slow sand filters; Calexico has long subsidence, coagulation and rapid sand filtration; while Brawley, Imperial, Holtville, Niland, Calipatria, Heber, Seeley, Dixieland and Westmoreland employ long subsidence only. Chlorination is practised by 6 of the cities.

The metropolitan district around Los Angeles is the important prospective user of the flood water to be conserved by storage behind Boulder Dam. When the construction of its 250-mile Owens River aqueduct was begun 25 years ago, the city of Los Angeles had a population of 160,000 and it was thought that the Owens River supply of 400 second-feet would suffice for two generations and a population of 2,000,000. During the past 15 years, a cycle of subnormal rainfall has been experienced during a period of unprecedented population growth, and far-seeing engineers have been warning the city that it was making an overdraft on its water resources. Realizing that ample water supply was vital for continued growth, Los Angeles filed claim for 1,500 second-feet of Colorado River flood water whenever it should become available, which is estimated to be enough for 7,000,000 people.

Surrounding cities, experiencing a similar rapid increase of population, and realizing the urgent need of an additional water supply,

Boulder Dam Symposium*

The Sanitary Engineering Aspect

LEON B. REYNOLDS

Professor of Sanitary Engineering, Stanford University, Stanford University, Calif.

THE Colorado River has been declared to be the largest remaining undeveloped asset possessed by the United States Government within the public domain. Certain it is that the river, if regulated and controlled, would be the source of great wealth and service, while in its present condition it possesses the power of great loss and destruction.

With a length of 1,750 miles and a drainage area of 242,000 square miles in the United States and 2,000 in Mexico, the Colorado ranks as our third largest river. Formed by the junction of the Green from southwestern Wyoming and the Grand from western Colorado, it has its main source in the rain and snow precipitated in the high Rockies. Leaving these altitudes, it flows through a succession of deep canyons receiving appreciable amounts of water from other tributaries, finally reaching the California line. Along the California-Arizona line south the river opens up into a series of narrow valleys of low altitude with arid climate, and eventually empties into the Gulf of California. For centuries the river has been building up a delta across the Gulf with the result that the north end which formerly extended to Indio was long ago cut off.

The flow of the present unregulated river at Yuma is subject to great variations; the annual discharge has varied from 8,000,000 to 26,000,000 acre-feet; and the average at the Black Canyon dam site (commonly called the Boulder Dam) is 16,200,000; variation in seasonal rate of flow is also great, from 1,250 to 200,000 second-feet actually measured and up to 500,000 estimated. Floods are deliberate rather than flashy in character, being due to melting snows, and occur from May to July; minimum flow occurs from September to December.

Use of the river for irrigation development has so far been made without a comprehensive plan for the entire stream. Some half dozen

cent; for year 1927-1928, minimum 0.03 per cent, maximum 2.92 per cent, weighted average 0.63 per cent. The figures for these 3 years show that the suspended matter may average as high as 10,000 p.p.m. with peaks as high as 138,000 p.p.m. It is reported that water in the Imperial canal system reached 26 per cent silt content in September, 1929. On the basis of a weight of 85 lb. per cu. ft. the U. S. Department of Agriculture estimates that the river carries past Grand Canyon an average of 253 million tons per year, or a volume of 137,000 acre-feet, as much as the total excavation removed by Americans from the Panama Canal; of this total some 15,000 acre-feet are deposited in the Imperial canal system, costing the farmers over \$1,000,000 yearly for cleaning ditches and releveling land. The Boulder Dam will provide storage of 26,000,000 acre-feet, allocated as follows: silt storage 7 million, water supply 10 million, flood control 9 million. If no upstream storage is developed in the meantime, this silt storage may be filled in 50 years and the entire reservoir in 200 years.

After the construction of the Boulder Dam a reservoir 90 miles long will be formed and, as soon as the velocity of the water is stilled in the reservoir, sedimentation will become effective. The 11 water systems in the Imperial Valley provide sedimentation periods ranging from 2 to 10 days, and tests of 222 samples by the California Department of Health showed 96.7 per cent average removal of suspended matter. At Calexico 3 to 5 days' storage is provided the year round, but it seems to be insufficient during flood season, possibly due to colloidal material; at Brawley, as a rule 95 per cent of the suspended matter goes down in 2 hours, but at certain times it will not settle in 1 or 2 days. Apparently it may be expected that rather complete clarification may be effected during the long storage behind the Boulder Dam. Therefore if Los Angeles should decide to tap the reservoir for its supply, a well clarified water should be available. If, however, the supply should be obtained by diversion without storage at some point far down the river toward Yuma, clarification would be necessary. Tests indicate that some of the silt carried by spring floods is now deposited in the 100 miles between Black Canyon and Topock. Silt in the lower river will undoubtedly persist for several years after the dam is built as the water picks up this accumulated silt and carries it onward. The Imperial Valley irrigation system will secure relief from its floods of silt as well as its floods of water, and the domestic water supplies will benefit likewise; some silt may be expected for the first few years as picked up below the dam.

The quality of Colorado River water as to chemical content is of interest from the standpoint of use for irrigation, for industries, and

joined Los Angeles in the formation of the Metropolitan Water District. A recent Los Angeles city bond election has provided funds for extension of the Owens River system, but it is felt that the Colorado River is the only source of sufficient magnitude for the future.

The District is now making surveys to determine the most feasible location for the diversion, and the choice seems to lie among four general routes varying from a long gravity line from the reservoir itself to a shorter line from the river below with high pumping lift (around 1,500 feet). We may assume that the probable diversion will be either from the reservoir itself or from the river below, somewhere between Black Canyon and Yuma.

The potability of the Colorado River water for domestic use is the question to be discussed in this paper. In the consideration of the quality of water for domestic uses attention should be given to the physical, chemical, and bacteriological content; some constituents may have significance only from the esthetic, some from the economic and some from the health standpoint.

PHYSICAL AND CHEMICAL CONTENT

Physical characteristics of water include its color, taste, odor, and turbidity. There would seem to be little likelihood of Colorado River water being colored, inasmuch as color is primarily due to dissolved organic matter and the drainage area is not characterized by heavy growth of vegetation, fully half being bare or scantily covered with desert shrubs and grasses. Taste and odor, due to growth in the reservoir of certain organic or plant life, particularly algae, cannot be predicted prior to actual storage of the water but seems unlikely and can be combated if necessary by aeration at the entrance to distribution storage, at the consumptive centers. Turbidity is a matter of considerable interest with reference to the Colorado River water, although suspended matter, taste, odor, and color are of only indirect hygienic significance.

The Grand Canyon has been called the greatest natural silt mill in the world, the silt produced being finely pulverized rock. The entire problem of the relation of Imperial Valley to the project may be said to be one of silt; the silt content has sanitary significance in connection with the necessary treatment of the water for domestic use. Tests of silt percentage by weight made by the U. S. Geological Survey at Grand Canyon gave the following results: October 1, 1925, to September 30, 1926, minimum 0.03 per cent, maximum 3.55 per cent, weighted average 0.56 per cent; for the year 1926-1927, minimum 0.04 per cent, maximum 13.81 per cent, weighted average 1.09 per

The chemical constituent of Colorado water about which there has been most controversy is chlorine. The content of common salt for the 3 years already quoted averaged 85 p.p.m. The U. S. Treasury Standard for salt content is 400 p.p.m. Various authorities place the border line where salt can be detected by taste from 200 p.p.m. up to 800 p.p.m., or even more. Collins of the U. S. Geological Survey says that few people can detect less than 600 to 800 p.p.m.; Whipple set the limit at 200 p.p.m.; and Dr. Wilson of Los Angeles at 400 p.p.m. Collins states that water may be considered good if it contains less than 400 p.p.m. salt. Accordingly the weighted average of Colorado water indicates that while the salt content of the present stream flow is considerable, nevertheless it would fall far short of the amount detected by taste.

The matter under controversy is not the present salt content but the probable salt content after the dam is built and the reservoir created. Salt deposits exist in the area to be flooded, especially in the Virgin River basin, and the probable effect of their submergence is a matter upon which geologists and engineers are not in agreement.

In 1922 Prof. Ransome, now of California Institute of Technology, made a preliminary study of the salt deposits for the U. S. Geological Survey and estimated that they might amount of 25,000,000 tons, most of which would be submerged. About 4 months ago he transmitted to the U. S. Geological Survey an extensive report based on a thorough reëxamination. He contends that the rock salt deposits are stratified; were deposited under arid conditions in a closed basin; and are exposed in cliffs varying in quality from pure to more or less silty salt. He contends that buried salt deposits if present are protected from solution by sediment; that the exposed area of deposits is generously estimated at 22 acres; and that the rate of solution after submergence would depend on area of contact, concentration of solution and temperature. In order to arrive at a rough approximation of rate of solution he performed experiments with blocks cut from the deposit which showed a beginning rate in standing water of 15 ft. per year, decreasing with longer periods of time. Assuming circulation of water in contact, no interfering silt blanket and no hastening of the process by porosity—none of which are in accordance with the facts—he determined that 15 ft. solution on 22 acres will increase the salt content of a full reservoir by 21 p.p.m. He considers this improbable and extreme even for the first year, and asserts that deposition of silt from the water and slumping of the overburden on the salt cliffs will seal the deposits and progressively decrease the rate. Other eminent geologists and engineers—the Colorado River Board, the Special Com-

for domestic purposes. The U. S. Geological Survey, since October 1, 1925, has been analyzing daily samples collected at Grand Canyon, Topock, and Yuma. An average weighted on the basis of quantity of flow indicates approximately the quality of the water held in a reservoir which would store all the flow and after the water was thoroughly mixed. Analyses at Topock and Yuma are very similar to those at Grand Canyon. The weighted averages for the years 1925-1926, 1926-1927, and 1927-1928 show comparatively little variation, and the figures quoted below are the straight averages of the weighted averages for these 3 years at Grand Canyon.

The total dissolved solids were found to be 528 p.p.m. and the average load of dissolved material carried by the river has been computed to be 31,370 tons per day. While the U. S. Treasury Standard sets the limit at 1,000 p.p.m., nevertheless the statement is made that "a water of the highest quality should have less than 300 p.p.m. of total solids and water with more than 750 p.p.m. is unsatisfactory for boiler purposes." Hence it must be recognized that the Colorado water is normally higher than desirable in dissolved mineral salts.

The average total hardness was 263 p.p.m.; bicarbonate radical was 161 p.p.m.; and sulphate radical was 208 p.p.m. The U. S. Treasury Standard for the latter is 250 p.p.m. Hence it may be seen that while the permanent hardness of the Colorado water is below the limit set, nevertheless it approaches the limit. No standards have been set by the U. S. Treasury Department for total hardness and opinions differ with regard to the proper adjective to apply to hardness. Probably due to the remarkable development during recent years in the field of water softening, there seems to be a tendency toward more rigid interpretations. In U. S. Geological Survey *Paper 496*, waters with hardness of 200 to 500 p.p.m. are classed as "hard to excessively hard," while Babbitt in his new text calls 230 p.p.m. "excessively hard" and 250 p.p.m. he calls "too hard for use."

There are now 110 cities in the United States furnishing a softened or partially softened supply, among which is Beverley Hills where a well water having a hardness of 200 to 340 p.p.m. is softened to 80 p.p.m. Until recently a reduction by the lime process of softening to 50 to 60 p.p.m. was considered as good as could be secured, but it is now possible to reduce carbonate hardness to 20 p.p.m. The public is realizing the advantages of soft water as well as clear and safe water, and indifference is being replaced by insistence upon soft supplies.

The iron content of the Colorado water averaged 0.23 p.p.m. while the U. S. Treasury Standard is 0.3 p.p.m., beyond which complaints of deposits and staining are to be expected.

regions offers no comparable alternative to the Colorado River as a source of complete supplementary supply.

Possibly for Los Angeles this is a case where "beggars should not be choosers."

BACTERIOLOGICAL CONTENT

There remains to be considered the bacteriological content of the water. Few data exist as to the number of bacteria present. The Yuma water supply is taken from the river to be settled and filtered. Results of 13 examinations by the Arizona State Laboratory from 1925 to 1929 showed the raw water averaging 4,070 bacteria per c.c., with extremes of 400 to 19,000; and the settled water averaging 510 per c.c., with extremes of 45 to 2,200; bacterial efficiency of plain sedimentation thus averaged 87 per cent. The sewage of Blythe is treated in Imhoff tanks and on natural sand filters and does not enter the river; the sewage of Needles, after Imhoff tank treatment and chlorination, enters the river some 220 miles above Yuma, and the sewage of Yuma enters the river without treatment below the city and above the headworks of the Imperial Valley canal system. In the case of Yuma the sewage is said to be diluted 30,000 times.

A sanitary survey of Imperial Valley water supplies made by the California Department of Health in 1922 yielded the following results. In monthly examinations at Calipatria, Calexico, El Centro and Niland from 1916 to 1922—211 samples—total bacteria averaged 2,300 per c.c., *B. coli* 2.5 per c.c., bacterial efficiency of sedimentation 98.8 per cent. It was determined that nearly all the contamination settled out in the first 2 days and that the water was probably safe after 5 days. Settling could apparently be relied upon to remove the greatest part of the contamination. The filters at El Centro and Calexico removed some bacteria but reliance could not be placed upon them for substantial protection.

The Imperial Valley canal water appears to be grossly contaminated at all times evidently caused by contamination within the Valley. The Colorado River contamination at Yuma, shown by total bacteria and *B. coli*, must be largely due to drainage from grazing lands since the only sewage is greatly diluted and enters the river a long distance above. There can be no doubt as to the need of filtration and chlorination of all the Imperial Valley public water supplies. Of course, they will benefit by the dam through the reduction in the amount of silt load requiring removal and in the mixing of water during storage resulting in an averaging of chemical content.

The water supply for Los Angeles will be desilted during its long

mittee of Los Angeles Chamber of Commerce, and the Metropolitan Water Board—share and agree with Prof. Ransome's opinions. The Metropolitan Water Board is now conducting detailed surveys and examinations of the locality.

As opposing the majority views may be mentioned E. C. LaRue, Hydraulic Engineer, and C. K. Fox, Consulting Engineer. The former believes that "the amount of salt carried at present is considerable and that any additional amount would be detrimental to agriculture where the water is continuously used for irrigation." The latter contends that the salt deposits were laid down in the bed of an ancient sea; that rock salt deposits exist 100 ft. thick and 30 miles long, that their amount may be as high as 25 billion tons; that the Colorado River and Virgin River gravel beds are salt-bearing and that 5,000 p.p.m. salt in the reservoir water may be the contribution from these sources.

The salinity of the reservoir water seems to be the constituent of most uncertain amount, but most authorities believe that the increase due to salt deposits will be inappreciable. However, any increase cannot be offset by any form of treatment; it has been said that anything can be removed from water except salt and politics!

From the standpoint of chemical content, therefore, the Colorado River water cannot be said to be first class. C. S. Howard in U. S. Geological Survey *Paper 636-A* says:

Clarified Colorado River water is nearly always satisfactory for drinking. It will serve for all ordinary domestic uses but does not attain the standard of quality generally demanded for a modern public water supply. The hardness of the water of the public supplies of Boston, New York, and many other cities is less than one-tenth of the average hardness of the Colorado water.

The Colorado River Board, consisting of five engineers and geologists, reported as follows:

The waters of the Colorado are normally high in dissolved mineral salts, chiefly carbonates, sulphates and chlorides. The amount is well within the limits of accepted practice for irrigation purposes. For domestic use the salt content is high; it is not an ideal water for such purposes but the fact that it is usable is demonstrated by its use in the cities of Imperial Valley and in Yuma and other communities along the lower Colorado.

Bulletin 17 of the California Department of Public Works. *Co-ordinated Plan of Water Development in Southern California*, contains this statement:

While the mineral content of Colorado River water is greater than would be desired if a choice in supplies were open, the lack of surplus water in the nearby

The Immigration Aspect

FRED T. FOARD, M. D.

*Acting Assistant Surgeon, U. S. Public Health Service, in Charge Western
Coöperative Rural Sanitation, Stockton, Calif.*

SOMEWHAT comparable in magnitude to the construction of the Panama Canal, the construction of Boulder Dam, whereby the world's greatest artificial lake will be formed, will be one of the largest engineering feats ever undertaken by the United States Government. We are told by the Department of the Interior that the time required to complete the task will be approximately 8 years, and the number of men employed at all times will be about 1,000. In addition to those actively engaged in construction work the families of employees and others drawn to the Boulder Dam townsite for business purposes will probably total a permanent population of approximately 5,000.

Located within easy reach of two transcontinental highways, one passing through northern Arizona and another through central Nevada, the Boulder Dam, with the widespread publicity given to it, will attract many thousands of tourists and employment seekers who will include it in their itinerary. It may be expected that a minimum of 25,000 to 30,000 people will visit the dam site each year.

At present no developments have been started, and as all lands along both sides of the Colorado River in the vicinity of future construction activities are owned by the federal government, the governmental agencies will be in a unique position as far as the approval of townsite plans, the termination of leases to those who may attempt to conduct non-legitimate business enterprises, etc., are concerned. Unlike conditions met with at similar large construction projects, it should be a comparatively easy matter to weed out the bootlegger, professional prostitutes, professional gamblers and other undesirables who are a detriment, from both a public health and economic standpoint, to the well-being of law abiding communities.

Climatic conditions in southern Nevada are considered to be altogether healthful. With the Boulder Dam, however, as the objective for many thousands of people, representing many nationalities and coming from all parts of this country as well as foreign countries, including Mexico and the Orient, it is certain that immigration problems will be met with which will require careful and continued public health supervision.

While no definite information could be obtained from the Secretary of the Interior as to the different nationalities which will be represented among the employees, I am grateful for information furnished through Dr. R. J. Stroud, Secretary of the Arizona State Department of Health, relative to nationalities employed in the construction of the Roosevelt and Coolidge dams in Arizona. Some information was also obtained from contractors who constructed several of the larger irrigation district and municipally owned dams in California. If the same policy of recruiting local labor is pursued at the Boulder Dam site as was carried out in the construction of smaller though similar projects in the Southwest, it can be expected that the proportions of nationalities represented will be about as follows: Mexicans 50 per cent, Indians 20 per cent, Filipinos not to exceed 2 per cent, and the remaining 28 per cent made up principally of Americans. There will in all probability be a few Chinese and a few Japanese who will be engaged in business enterprises of one kind or another.

Plans have already been drawn for the construction of the Boulder town on a permanent basis, with consideration given to proper ventilation and heating systems for all dormitories and other living quarters. A safe water supply and a sanitary method of sewage disposal have also been provided for, both of which will be built according to the specifications of experienced sanitary engineers.

DISEASE CONTROL

To obtain the best results in the prevention and control of disease will require close coöperation on the part of officials in charge of construction operations with federal, local and state public health and police officials. With the probability of many Mexican laborers, few of whom will have been vaccinated, considerable smallpox can be expected and some typhus may be met with. While vaccination cannot be made compulsory under the state laws of Nevada or Arizona except in time of a pending epidemic, a requirement on the part of employers for anti-smallpox vaccination for all non-immune applicants for employment would be a master stroke in the prevention of this disease, and may result in a great economic saving for employer and employee alike. Such a policy is now being carried out by the Southern Pacific Railway Company and has met with little opposition from trainmen and others affected by the ruling.

With the high prevalence and widespread distribution of epidemic cerebrospinal fever in the western states during the past few years it can be expected that some cases may be met with among the Boulder Dam population. Due to their high susceptibility and their tendency

to crowd together in close sleeping and living quarters, meningitis has been particularly prevalent among Filipinos in the Rocky Mountain and Pacific Coast states during the past two years. Should any considerable number of Filipinos be employed or become residents of the Boulder vicinity, careful and constant supervision of sleeping quarters will be necessary to prevent the spread of this disease.

Trachoma is very prevalent among the several tribes of Arizona Indians, many of whom will probably be employed as laborers by the construction companies. While these people will prefer to live in their tepee tent colonies away from other employees, constant vigilance will be necessary to prevent the spread of trachoma among school children. The Indian is also very susceptible to both measles and tuberculosis. For the control of these diseases and the general health of the Indians, as well as for the protection of those with whom the Indians will come in close contact, best results can be obtained through a public health nursing service. It would be preferable if an Indian nurse or one who has had previous experience with Indians could be employed for this duty. Careful sanitary supervision will also be necessary for Indian colonies in order that body excretions may be properly disposed of and the spread of typhoid and other intestinal diseases prevented.

Bacillary dysentery has been particularly prevalent in the Southwest during recent years. Hundreds of cases have been seen in the Salt River Valley in Arizona during the past three years, and it cannot be expected that the Boulder Dam district will completely escape this infection. In addition to the maintenance of a safe municipal water supply for the town and vicinity, careful and continued inspection and supervision of raw food supplies should be carried out. In view of the very hot weather in southern Nevada during the summer months, proper refrigeration facilities are essential and should be required for all food dispensaries.

MILK AND DAIRY PRODUCTS

In that neither southern Nevada nor northern Arizona is a milk producing area it is probable that the major portion of milk and milk products used at the Boulder Dam site will be provided from distant points, though some will be supplied from small dairies in the immediate vicinity. It will be necessary, therefore, that provision be made for the inspection and sanitary supervision of all dairies furnishing products to the people of the Boulder district. Unless such provision is made there will be constant danger of epidemics of diarrhea and enteritis, typhoid fever and other milk-borne infections.

Regardless of the degree of vigilance of the police and public health officials there will probably be a considerable venereal disease problem to be met. Although open prostitution may not be permitted, clandestine prostitution will be certain. For effective venereal disease control, continued and close coöperation between police and public health officials will be necessary. For the treatment of venereally infected patients a free treatment clinic should be maintained as a part of the routine program. An anti-venereal disease educational program should be carried on and should include the distribution of information through posters, pamphlets, lectures, the showing of moving picture films, etc. The literature distributed on the subject should be printed in as many languages as necessary.

IMMUNIZATION AND VACCINATION

It is probable that compulsory vaccination and immunization cannot be legally enforced in either Nevada or Arizona. If, however, the construction companies can be induced to require all employees to be vaccinated against smallpox and immunized against typhoid fever prior to or immediately after employment the control of these diseases will be greatly simplified and undoubtedly a great economic saving will be accomplished. Both anti-smallpox vaccination and anti-typhoid immunization, without cost for the service, should be offered to and urged upon all residents of the Boulder Dam area. Anti-diphtheria immunization should also be provided without cost for all children of preschool and school age.

Southern California county health officials and state and county health officials of Arizona advise that expenditures for the care of the indigent sick in the Southwest are a very heavy tax upon county and municipal appropriations for health purposes. In many instances funds appropriated for preventive measures are diverted for use in supplying food and medical care for indigents who have contracted preventable diseases, particularly smallpox and typhoid fever, in eastern or central western states or in Mexico, and have become ill while migrating to the Rocky Mountain or Pacific Coast states in search of employment, the restoration of health, or for other purposes. Certainly the indigent tourist is a considerable economic problem of many counties throughout the Southwest and every effort should be made by officials in charge to discourage prolonged visits of itinerants to the Boulder Dam site.

When the necessary personnel has been recruited widespread publicity should be given through the press that additional employees are not needed. Otherwise there will in all probability be a continuous

pilgrimage of wandering citizens headed for Boulder Dam during the period of construction. Most of these people will expect to live in tents by the roadside and at so-called automobile camps. Most of these camps are grossly insanitary, and constitute a serious public health problem. Typhoid fever, smallpox and other communicable diseases may be expected among these people and when they occur little can be done to control their spread.

HYGIENIC LABORATORY FACILITIES

The weekly bacteriological analysis of water and milk supplies, the examination for suspected diphtheria and tuberculosis cases, the diagnosis of venereal disease infections, and the routine running of Wassermann or Kahn tests, together with other necessary routine laboratory work, should justify the establishment of a hygienic laboratory at the site of construction. A single laboratory should be able to carry on all necessary work for the two counties adjacent, one in Arizona and one in Nevada.

ISOLATION AND HOSPITALIZATION

While hospital facilities are being provided for in the plans for the town which will be constructed for employees and their families, provision should also be made for the isolation and segregation of communicable diseases. An attempt to quarantine or isolate patients suffering with communicable diseases in dormitories, roadside tents or automobile camps, will be unsatisfactory and will constitute a serious health menace to the people of the local community and to those of nearby cities and towns and surrounding states.

OFFICIAL SUPERVISION

While the actual construction of the Boulder Dam will be carried on by private companies who will be under contract with the federal government, the dam itself and all the land in the immediate vicinity, including the townsite in which employees and their families will live, will be government owned property and under government supervision. For this reason it may properly be expected that the greater portion of the expense for maintaining health supervision should be borne by the federal government. Since this supervision will have to be carried out in accordance with the laws of Nevada and Arizona, however, a coöperative agreement should be arranged between federal, state, and local health officials whereby each may share in the responsibility of supplying an adequate and effective health service.

As surrounding communities will be directly affected by the prev-

alence or non-prevalence of preventable disease in the vicinity of the Boulder Dam during construction, and it will be an attraction for tourists for all time, it seems that public health supervision should be established on a permanent basis and organized to include the whole of the two adjacent counties, one in Arizona and the other in Nevada.

In order that health policies may be uniform it may be advisable for a single executive to be placed in charge of their formulation and the direction of public health activities. If legal technicalities should make it impossible for a single director to serve in two states, individual health officers for the respective counties could be appointed as assistants to the chief executive or director. The chief director and his assistant county health officers should, alike, be satisfactory to and approved by state health officials and local county officials.

While the above plan is merely suggested for consideration it is believed that through some such organization an efficient health service could be given, not only to those people in the immediate vicinity of construction activities, but to residents and transients alike on a county-wide basis. While it is impossible to estimate accurately at this time the cost of such a health service it is probable that efficient service could be given by a minimum health department personnel for the Nevada county, consisting of a county health officer, two experienced public health nurses, one sanitary inspector, a laboratory technician and an office clerk. For the Arizona county a minimum personnel to include a county health officer, one experienced public health nurse, and an office clerk would probably be sufficient.

In view of the limited normal populations in both of the counties concerned, and in that the greater portion of the time and work of the personnel of the respective county health departments would be given to the immediate vicinity of construction activities, it would be only reasonable to expect that the state and local governments should bear a minor portion of the expenses incurred for public health supervision. Provision, however, should be made looking toward the eventual taking over of the county health departments by the state and local governments. With the federal government providing for the salary of the director in charge, together with furnishing office space and equipment for the personnel of the two county health departments, it is probable that a well rounded public health program on a county-wide basis could be worked out whereby additional funds to provide for salaries and maintenance of field personnel could be borne in suitable proportions by county officials, the state departments of health, the Division of Rural Sanitation of the U. S. Public Health Service, and possibly to some extent by coöperation from the Rockefeller Foundation or other private agencies engaged in public health work.

Problems of Sanitation at Headquarters Area During Construction of Boulder Dam

H. B. HOMMON, F. A. P. H. A.

Sanitary Engineer, U. S. Public Health Service, San Francisco, Calif.

THE Boulder Canyon project act (45 Stat., 1057) approved by the President, December 21, 1928, authorized, subject to future appropriations, the construction of a reservoir of not less than 20,000,000 acre-feet capacity on the Colorado River, the dam to be located at either Black Canyon or Boulder Canyon. It has been decided to locate the dam in Black Canyon (see map), approximately 20 miles downstream from Boulder Canyon. This location is about 30 miles southeast of Las Vegas, Nev., and 65 miles northwest of Chloride, Ariz., shipping points, respectively, on the Union Pacific and Santa Fe Railroads. The river at this point is the boundary line between Arizona and Nevada.

The situation with regard to the construction work at this time is explained in the following quotation from Dr. Elwood Mead, Commissioner of Bureau of Reclamation Service:

Plans for the town are awaiting an appropriation of funds by Congress with which to begin construction work. At the present time, therefore, there is very little information available, as the town site has not even been laid out.

The Act of December 21, 1928, authorizes an appropriation of \$165,000,000 to carry out all the work contemplated, and Congress has been requested to make available immediately \$10,660,000 to build a town and provide the necessary utilities; to build railroads and highways; provide necessary equipment; and start preliminary work on the diversion tunnels.*

In order to obtain a proper perspective regarding the size of the Boulder Dam project and the magnitude of the problems of public health confronting the United States Government and the states of Nevada and Arizona, there will be given a few facts from official papers of the Reclamation Service. The dam will raise the present water surface 550 feet and the structure will have a total height of about 700 feet. The reservoir behind the dam when filled will be

* About June 15 \$10,660,000 was appropriated for this work.

approximately 110 miles long, and the amount of water stored will be sufficient to cover the state of Kentucky one foot deep. This will be the largest artificial body of water in the world.

The top of the dam will be a bridge connecting the transcontinental highways passing through Las Vegas, Nev., and Kingman, Ariz. It is anticipated that the time required to construct the dam and other structures connected with it will be between 7 and 8 years and the average number of employees with their families will be about 4,000. In addition to this number there will be a scattered population in camps, hotels and amusement places along the highways in Nevada and Arizona near the dam site and most likely the population of Las Vegas, Nev., and Chloride and Kingman, Ariz., will be materially increased.

A definite policy has not been decided upon regarding concessions and responsibility for providing housing for workmen and their families. It is stated, however, that:

On contract work the general contractor usually supervises, controls, and operates the major concessions, especially those located in the construction camps, such as commissary, dormitories, mess houses, hospital, etc. Should it be considered advisable to grant a limited number of concessions to others, a suitable area may be set aside in a town site for such purposes. Under present regulations it is customary to grant such privileges only under competitive bids received after public advertisement.

Plans are being made for a town on the brink of the Colorado River for the housing of the workmen who will construct Boulder Dam, and of their families and the normal population necessary to their comfortable existence. The town will be located on government land. The government will retain ownership of the land and lease it to those who live on it or use it for commercial purposes. One of the features of these leases will be that they will continue only under the period of good behavior of the tenant. It is the intention of the government that the bootlegger or other law violator shall not interfere with the well-being of its workmen while assigned to this huge task. The power to terminate leases, and therefore residence, in this town will be used as one of the means of enforcing proper conduct.

WATER SUPPLY

The only source of water supply is the Colorado River, which is 800 feet below the proposed town site. The suspended matter in the water varies from a maximum of 4,400 p.p.m. during flood stages to 300 during low water, and the hardness varies from 150 to 530 p.p.m. The town of Yuma, located several hundred miles downstream on the river, uses the water for domestic purposes after treatment by settling, coagulation and passage through rapid sand filters. Above Yuma, however, the river passes through low land where considerable sediment is deposited and the problem of removing sediment at the dam

COLORADO RIVER BASIN
AND
SURROUNDING TERRITORY

site will be more difficult than at Yuma. The government has for several years been making turbidity and other analyses of water taken from the river in the Canyon above the site of Boulder Dam and the data available will be valuable in designing a water treatment plant. It has been estimated that the initial developments will cost approximately \$100,000. This, however, does not include force mains and distribution system and storage tanks.

Outside of the area set aside for the town site, there will be located on privately owned or leased land, stores, hotels, camps and amusement places, all of which will have to be supplied with water hauled in tank cars or furnished by the government. Since many of the laborers who will be employed at the dam may live a part or all of their time outside of the town, and since the employees at the dam will mingle with the people living outside the government area, an adequate and pure water supply should be provided not only for the town but for all places that are built up outside and are operated in connection with the work at the dam. This brings up a rather complicated problem of public health since it involves the authorities of the government and the states of Arizona and Nevada.

SEWAGE DISPOSAL

No plans or estimates have been made by the government for a sewerage system or treatment plant and no contour map of the area where the new town will be located is available. The country is hilly, arid, sparsely settled, and the only towns diverting water from the Colorado River for domestic purposes are Needles, about 100 miles downstream, Yuma, approximately 250 miles, and El Centro, which takes water from an irrigation canal beyond Yuma. The large dilution factor in the river water together with the long distance before water is diverted for domestic purposes will permit the discharge of partially treated and disinfected sewage into the river, and the nature of the topography of the land and climatic conditions may be favorable for broad irrigation.

The Reclamation Service can locate the town site with a full knowledge of the responsibility for providing water and taking care of sewage for a fairly definite number of people located in one place; but outside and nearby the town site there may develop a serious public health problem in providing adequate sewage disposal for the people attracted to the dam either as prospective laborers or as operators providing services or amusements. With the present labor conditions throughout the country, workmen from every state and from Mexico may go to Boulder Dam in large numbers, and the only places they

can live outside of the new town will be in camps or hotels established along the highways. If it is not practicable for the government to furnish water under pressure to the communities that develop on both sides of the river and beyond the government areas, it will be necessary for the state or county officials of the two states concerned to require installation of either chemical toilets or can privy systems with organizations to take care of them properly, or earth pit privies properly designed.

GARBAGE DISPOSAL

The problem of collecting and disposing of garbage and rubbish from the new town and construction camps will be similar to permanent towns of the same size and general location. Although isolated areas are available for disposing of garbage, refuse and tin cans, it is believed that it will be more economical and practical to burn the garbage and bale the tin cans. An incinerator and baling machine of the type used by the National Park Service in the National Parks would be satisfactory for the population anticipated in the new town.

Outside the area under the jurisdiction of the Reclamation Service; there will develop along the highways a problem of collecting and disposing of garbage and refuse from tourist camps, hotels and other places. This problem, however, will no doubt be handled in accordance with some general plan that will be adopted for supervision over sanitation in all the territory adjacent to the dam site.

INSECT CONTROL

Malaria exists in southern Nevada and in Arizona and it will be carried to the dam and neighboring territory by employees and tourists. It will be necessary, therefore, at the new town to prevent the breeding of mosquitoes by covering and screening storage reservoirs and to eliminate or oil all vessels of any kind or catch basins that will hold water, and to design and operate the sewage treatment plant so that mosquitoes cannot breed in the sewage. In order to control malaria at the dam, however, it will be necessary to prevent breeding of mosquitoes in the areas in Arizona and Nevada adjacent to the dam as well as the territory immediately around the dam.

The extent of a fly nuisance or menace to health will depend upon the efficiency of the organization and equipment for removing at regular intervals garbage, refuse, stable manure, and the construction of earth pit toilets so that flies cannot enter them.

It is not only possible but practicable to reduce the breeding places of mosquitoes and flies to a minimum and to screen houses to prevent

the entrance of these insects. It would appear, therefore, that the only problem involved in this matter is an organization to handle the work and the coöperation of the three different authorities having jurisdiction.

FOOD SUPPLIES

There will be constructed a branch railroad line from the Union Pacific System at Las Vegas to the new town at the dam on the west side of the river and possibly another branch from Chloride on the Santa Fe lines to the east side. This will insure delivery of food supplies in proper condition directly to the dam. The main problem, therefore, in connection with the food supplies in relation to public health will be the handling of the food after delivery. Since the temperature at the dam site varies from a minimum of 20° F. to a maximum of 120° F., it will be necessary to provide adequate refrigeration for perishable foods and to inspect at regular intervals all places storing, handling and serving food products.

CONCLUSIONS

The Reclamation Service has constructed large dams in the Southwest and is familiar with the problems of public health that develop in a large population gathered together from different sections of the country in a new town or camps. The situation at Boulder Dam, however, differs from the construction at other dams, because of the size of this project and the location on the boundary line of two states. As already stated, there will be approximately 4,000 people living at the headquarters area and other places on government owned land, and in addition there may be a large number of people living outside the government areas but adjacent to them in Arizona and Nevada. All of these people will form one large community, but authority over public health will be divided between the officials of the government and the states of Arizona and Nevada. It would appear, therefore, that it will be necessary to establish efficient health organizations in the counties of Arizona and Nevada bordering on the area around the dam, and for the health officials of these two counties and the government to work in close coöperation. If appropriations cannot be obtained in the states for carrying on the necessary health work, the government should either provide the necessary funds or work out a plan with the health officials of these two states whereby the Reclamation Service would accept the responsibility for sanitation and other matters pertaining to public health in a limited zone around the headquarters area.

DISCUSSION

R. J. STROUD, M. D.

Health Officer, Phoenix, Ariz.

DR. FOARD asked me to say a word about Indians. In Arizona projects—and there have been five major ones, four in Salt River and one on the Gila River—we have employed an average of 22 per cent Indians. Whether in a project as large as this there will be that many Indians, we do not know, but if there should be, we will have quite a problem.

There are several kinds of Indians. The good fighters are the good workers. The Apache is a wonderful worker. Contractors in that section like to have the Apache Indians as laborers. They have never built permanent places for they are not farming people as are the Pimas, Maricopas, and others. They want to go out and work, but insist upon one thing, and that is that they live by themselves in their own communities. During all of our constructions, the Indians were given home sites in a little canyon where they could be by themselves.

Indians and Mexicans get along very peaceably with the flies. They do not make any attempt to kill them, but seem to feel that they are just a part of their daily bread. If the Indians are restricted in any way, they will simply move just outside of the government franchise, for they will live their own lives. While they like work, they believe in the women doing the work at home. The smoke curls through the ceiling of their tepees, and they chop their wood long and burn the end only, the other end protruding outside. Where this little piece of wood passes in there is going to be a fly menace—an opening where flies can go through.

The next problem is the Indian child. Primitive races have tuberculosis young. They do not die at 18 to 25 years of age, but from 6 to 14. At least 25 per cent of these children can be proved tuberculous by the stethoscope. Because it is natural for children to fraternize, these children will mix with other children, especially if they are put into the same schools.

While the Indians will tolerate inoculation, they will not stand for segregation. There are some things you cannot do with an Indian, and this is one of them. If you try to pin a measles sign on his door, he will just move right out. This is a problem you will have—spreading tuberculosis, trachoma, and venereal diseases among his own people, and then going out and mixing among the other people under a very loose control.

LEON B. REYNOLDS

MOST of those who have felt that the increase in salt content would be inappreciable have based their conclusions partially on the slow solution of salt in the salt cliffs, partially on the feeling that the silt content of the water itself would settle out and cover up those beds with a blanket, or silt cover, which would prevent further solution, and partially on the belief that the silt cover which is on top of those cliffs would prevent further solution. As far as the silt blanket is concerned, it seems to me that the silt coming from the Colorado itself will naturally be deposited as soon as the water is stilled, which would be up at the upper end of the 90- or 100-mile reservoir, and that probably only small portions

of it would continue down as far as the point where the Virgin River empties, probably fifty or sixty miles from the upper end of the reservoir. For that silt to continue in the water down as far as the entrance of the Virgin River seems to me rather unlikely. On the other hand, silt from the Virgin River might be useful in providing a silt bed on those salt cliffs. I am not very familiar with the characteristics of the Virgin River as to whether it carries sufficient silt to accomplish that or not.

The engineers who have studied the proposition have decided that the best location for the dam, all things considered, is at the Black Canyon, at least for the first development, that it would be more useful due to being nearer the center of power distribution, and better for de-silting of the river at that location than at the Bridge Canyon site.

RESOLUTION NO. V

*Adopted by the Western Branch of the American Public Health Association,
June 14, 1930*

WHEREAS, the construction of the Boulder Dam will present inter-state health and sanitary problems involving the United States Government and two sovereign states; and

WHEREAS, certain contracts may be let to private contractors for construction of various units of the dam; and

WHEREAS, the health and sanitary problems developing will directly or indirectly affect the local population as well as that in the surrounding states, now therefore be it

RESOLVED, that it is the sense of the Western Branch of the American Public Health Association, now in session in Salt Lake City, that the importance of these problems which will develop be given careful study by the Secretary of the Interior, the Surgeon General of the U. S. Public Health Service, and the State Health Departments of Arizona and Nevada, with the view to consolidating their efforts into a uniform plan of procedure; and be it further

RESOLVED, that it is recommended that such coördinated activities be agreed upon in advance of construction work.

Milk-Borne Disease in Massachusetts, 1927-1929*

GEORGE H. BIGELOW, M. D., F. A. P. H. A., AND
FILIP C. FORSBECK, M. D.

*Commissioner, Massachusetts Department of Public Health; and Research Fellow,
Harvard School of Public Health, Boston, Mass.*

PREVIOUS chronological reports of milk-borne disease in Massachusetts^{1,2,3,4} have been published covering periods of from three to eight years. During the past three years the menace of inadequately protected milk supplies has been more forcibly brought to attention than ever before, particularly because of an outbreak of septic sore throat resulting in 48 deaths.^{5,6,7,8} Moreover, progress in the protection of milk supplies has been more rapid in Massachusetts than ever before. It is thought desirable, therefore, to bring previous data up to date at this time, and to increase the number of items studied. Certainly it is utterly futile to carry on an intelligent program among laymen, producers, dealers, and boards of health, without being able to present the facts about the current milk situation. Many groups rightfully expect the State Department of Public Health to be a clearing house for this type of statistical information.

Questionnaires covering the year 1928 were sent to the 125 Massachusetts cities and towns of over 5,000 population, which represent over 90 per cent of the entire population of the state. Replies were received from 95 communities, 76 per cent of all those receiving the questionnaires. These communities represent 83 per cent of the total population of the state. In previous reports only communities of over 10,000 population were studied. We have found that the towns in the 5,000-10,000 group have, as a whole, been unable to supply satisfactory information relative to the milk situation in their respective towns. It is our opinion that most progress is needed in this group at the present time. The group has a population of about 400,000, and yet has a milk supply which, in general, is very poorly protected.

Table I gives information relative to the towns answering the questionnaire.

In Table II are listed the total reported cases of certain diseases by years, the number, and the percentage traced to milk. There is

* Fifth Chronological Report from the Massachusetts Department of Public Health.

undoubtedly considerable error in this set of figures. For example: Septic sore throat was not made reportable until 1914; morbidity reporting is far from perfect, and varies in its accuracy with different diseases; it is frequently impossible to state the exact number of cases due to milk-borne disease; and finally, small obscure outbreaks might be missed entirely.

Nevertheless, there are several interesting trends which are worth noting. Since 1906 there has been a decrease of milk-borne disease at the rate of about 12 per cent per year, if the Lee outbreak is not included, and at the rate of about 5 per cent if it is included. The percentage of diphtheria and of septic sore throat traced to milk has remained fairly constant, although in the latter case the period is too short to be of much value statistically. During the period 1906-1929, the percentage of scarlet fever traced to milk decreased at the rate of about 15 per cent per year, while during the period 1896-1929 the percentage of typhoid fever cases traced to milk increased at the rate of about 5 per cent per year.

This difference in typhoid fever and scarlet fever trends may be logically accounted for in this way: Typhoid fever is being dealt with so successfully in other ways that, in spite of the increasing amount of pasteurized milk, the disease is finding milk to be more and more its stronghold as compared with water, for example. In the case of scarlet fever, however, efforts up to the last two or three years have been almost futile, probably the only real advance being the protection offered by the increased use of pasteurized milk. Hence the decline in the percentage of cases traced to milk.

Table III shows the seasonal distribution of milk-borne disease by cases and outbreaks over a period of 44 years. The curve is bimodal, the first and minor peak occurring in April because of the prevalence of septic sore throat and scarlet fever outbreaks, and the second and major peak in August and September because of the prevalence of typhoid fever outbreaks. In each of the four diseases studied, about

80 per cent of the outbreaks occur in one-half of the year. This period is blocked-off in Table III and is summarized in Table IV. It is interesting to note that scarlet fever and septic sore throat, which have so many common characteristics, are alike in the seasonal distribution of milk-borne outbreaks. This fact has been noted by Scamman for the state as a whole.⁹ We have no explanation for the fact that the milk-borne outbreaks of diphtheria tend to occur at the opposite time of the year to the general incidence.

In the case of typhoid fever, the seasonal distribution of milk-borne outbreaks cannot entirely be accounted for on the basis of an increase of general incidence. Many of the outbreaks are due to carriers, and their number may be presumed to have no seasonal variation. Table V contains information relative to typhoid fever outbreaks caused by cases and by carriers. It shows that outbreaks due to carriers have a seasonal distribution similar to the typhoid fever curve of general incidence. The seasonal increase is probably due to one or more of the following factors:

1. Increased vulnerability of the milk
2. Increased output of *B. typhosus*
3. Increased virulence of the organism
4. Increased susceptibility of the individual

Vulnerability of the milk supply is certainly a minor factor if it plays any rôle, since the peak is not coincidental with the heat peak. To study the bacterial output of carriers by seasons would give information which might throw considerable light on the epidemiology of typhoid fever.

As a matter of fact, the median outbreak due to a carrier occurs about two weeks before the median outbreak caused by a case. The

Third 16 outbreaks	7	44	9	56
Fourth 16 outbreaks	3	19	13	81
	31	48	33	52

only explanation we can offer is that of recent years there have been more outbreaks due to carriers, and the more recent outbreaks have been occurring earlier coincidentally with an earlier seasonal distribution. The possibility of such changes has been noted by Rosenau¹⁹ and by Mills.²¹

The recent increase in the relative number of outbreaks known to be caused by carriers is illustrated in Table VI. The explanation is two-fold: Only in recent years have we become actively cognizant of carriers, and each year greater effort is made to find them. The number of carriers is not decreasing so rapidly as the number of cases.

In Tables VII and VIII are shown the relative frequency of cases and outbreaks, respectively, of the four diseases considered. These tables show that, of milk-borne disease in Massachusetts, there are more outbreaks of typhoid fever, but more cases of septic sore throat. If just the past twenty years are considered, septic sore throat is still more relatively important.

Since 1911, outbreaks and cases have been decreasing at the rate of about 10 per cent per year, if the Lee outbreak is included; while cases have been decreasing at the rate of about 16 per cent per year, if the Lee outbreak is excluded. In other words, outbreaks are becoming limited to smaller dealers as time goes on, largely because of the fact that pasteurization is being more fully utilized by the larger dealers. The dilution incident to the larger supplies may also be a factor. In a period of about twenty years, the case rate of milk-borne disease has been about 41 per cent higher in communities under 10,000 population than in communities over 10,000. This reflects the high percentage of protection offered by pasteurized milk in the larger communities.

1926-1929	10	1,326	133	29	22

^a Including only those outbreaks for which the number of cases is known more or less accurately.

In Table IX are listed those outbreaks for which the number of cases are fairly definitely known. From this table we have calculated the mean number of cases and outbreaks by quinquenniums. The average number of cases per outbreak has been increasing at the rate of about 1.6 per cent per year. This increase in the mean number of cases per outbreak is due entirely to the tremendous outbreaks of septic sore throat in recent years. As a matter of fact, the median outbreak is decreasing as would be expected when one considers that the larger milk dealers take up pasteurization with greater readiness than the smaller ones. If one includes the septic sore throat outbreaks, the size of the median outbreak since 1886 has been decreasing at the rate of 1.8 per cent per year; while if septic sore throat is not included, the size of the median outbreak has been decreasing at the rate of 3.3 per cent per year.

* Milk placed in 20- and 40-quart cans after pasteurization and infected by a carrier who as a food handler transferred the milk from the cans to the cups of patients in an institution for mental disease.

NOTE: Some cases never officially reported, but found by special investigation.

Table X lists the outbreaks traced to milk in 1927, 1928, and 1929. Nineteen twenty-nine is the first year since the first outbreak of typhoid fever was reported, in 1886, that has not witnessed an outbreak of milk-borne typhoid fever. There has been no outbreak of milk-borne diphtheria for four years.

Table XI shows the per capita consumption of milk. No significant change in this is noted, although the value of milk as a food is being urged in the schools and elsewhere. It will be seen that the reported per capita consumption is greater in the larger communities. It is not known whether the per capita consumption is greater in rural or urban communities. Undoubtedly the figures are greatly influenced by the fact that home consumption of home production is not included in the milk statistics of boards of health. The per capita milk consumption is an important measuring stick from both commercial and health points of view, and we are convinced that the

questionnaire is not accurate enough to be satisfactory for this purpose. The U. S. Department of Agriculture, working in collaboration with the State Departments of Agriculture, of Conservation, and of Health, are planning periodic surveys which will give this information with greater accuracy.

The milk consumed in Massachusetts is produced in the New England States, New York, and Quebec. It is estimated that 62.4 per cent of the milk consumed in the communities answering this item of the questionnaire is produced in Massachusetts.

As one would expect, the percentage of home production increases quite uniformly with the decrease in the size of the community. Thus, in communities of over 50,000 about 40 per cent of the milk is imported from other states, while in the communities of 5,000 to 10,000 about 14 per cent is imported from other states.

A very encouraging item is the continued increase in the percentage of pasteurized milk. There has been a substantial increase in each of

TABLE XII

COMMUNITIES IN MASSACHUSETTS WHICH REQUIRE THAT ALL MILK BE EITHER PASTEURIZED OR FROM TUBERCULOSIS-FREE CATTLE (1929)

Group	Number of Towns in Group	No. of Towns Having Reqm.	% of Towns Having Reqm.	Pop. of Group	Pop. having Requirement	%
50,000—Over	18	15	83.3	2,413,960	2,123,788	88.0
25,000—50,000	12	8	66.7	471,157	315,592	67.0
15,000—25,000	27	13	48.1	513,533	261,278	50.8
10,000—15,000	18	8	44.4	219,033	98,093	44.7
5,000—10,000	52	9	17.3	372,634	66,641	17.8

the population groups considered, and while for all the groups the total percentage has increased from 83 per cent to 85.7 per cent, the total for the first four groups has increased from 83 per cent to 87 per cent. Almost 25 per cent of the milk sold raw in communities of over 10,000 in 1926 is now pasteurized. As one would expect, the percentage of pasteurized milk is highest in the larger communities. The range is from nothing to over 99 per cent. However, some of the smaller communities are outstanding in the exceptional relative amount of pasteurized milk used. This is very encouraging, but on the other hand it is very discouraging to note that in a number of large cities the per cent of pasteurized milk ranges around 40 to 50 while other cities of corresponding size have more than 99 per cent of their milk pasteurized. When we consider that, in general, the larger routes are in the larger places, we realize (thinking quantitatively) that the menace of milk-borne disease is concentrated in a few particularly lax, fairly large communities.

The percentage of certified milk has increased from about 0.6 per cent to about 1 per cent. Because of the small figures this information is not so accurate as for pasteurized milk, but undoubtedly there has been an increase in the use of certified milk. It is of interest that this increase has occurred to a greater extent in smaller communities.

Of the 355 cities and towns in the state, 208 (58.6 per cent) report having some milk inspector. All communities over 25,000 so report, but there are 12 between 5,000 and 25,000 without any. Surely this is not good! Moreover, milk inspection, when it does exist, is as poor in some communities as it is good in others.

In 1926, communities giving this data report 10.3 chemical and 4.9 bacteriological examinations per 100,000 quarts of milk, while in 1928 the figures are 10.4 and 5.4, respectively. They report that 13.1 per cent of the samples of raw milk not intended for pasteurization showed counts over 300,000 per c.c. It is distressing that a number of communities allow milk to be sold raw which under our present regulations would not be accepted for pasteurization. In 55 communities the average percentage of total solids was 12.59, while from 62 communities the per cent of butter fat was 3.81. In general, these figures increase somewhat from larger to smaller communities.

Table XII shows the communities in Massachusetts, by population groups, which require that all milk be either pasteurized or from tuberculosis-free cattle. We have reached the paradoxical situation in which it is safer for children to secure their milk in most urban communities than in most rural communities.

SUMMARY

This report is based upon data from 95 of the 125 communities over 5,000 and covers 3,604,314, or 83 per cent of the entire population of the state. We are impressed that the smallest of these communities have almost no protection of their milk supplies.

The proportion of all typhoid fever traced to milk has been increasing markedly, while for scarlet fever it has been decreasing. Over the period of 34 years, the four diseases considered range themselves by outbreaks in the following order of magnitude: typhoid fever, scarlet fever, septic sore throat, and diphtheria; but by total cases in the following order of magnitude: septic sore throat, typhoid fever, scarlet fever, and diphtheria. As pointed out in our preceding report,⁴ the rate of decrease of total cases spread by milk is greater than the decrease of outbreaks so spread. This suggests that fewer persons are exposed to each outbreak, and that therefore they tend to occur in a higher proportion of instances on smaller milk routes than formerly. This bears out the evidence that the smaller dealers less frequently protect their milk by pasteurization.

Nineteen twenty-nine is the first year, since the first outbreak of typhoid fever was reported, that has not witnessed a milk-borne outbreak of this disease. There has been no outbreak of diphtheria for four years.

Although the data are open to question, there is no evidence of an increasing consumption in milk over a 10-year period, in spite of the intensive health and commercial propaganda on this subject. As would be expected, the proportion of Massachusetts produced milk increases with the decreasing size of the community.

Since 1919 there has been an encouragingly marked increase in the proportion of milk pasteurized, in general being higher in the larger communities. On this, more than any other single factor, must we depend for the eventual obliteration of milk-borne disease.

Although the figures are too small to be of much significance to the public health, the apparent increase of certified milk would suggest a growing realization that if raw milk is to be consumed, it must have the maximum protection. The recent discussion of certified-pasteurized milk, which to us seems to be the ideal milk, leads to the hope that this product may eventually become a factor in our milk supply.

It is shocking to learn that 147, or 41.4 per cent of our communities, have no shadow of an inspector of milk, the most important and vulnerable of our foods. When we see that 12 of these communities have populations over 5,000, our patience is well nigh exhausted, particularly if we consider also the number reporting inspection which is gravely inadequate. In the last two years there has been a slight increase in the protection offered by the bacteriological examination of milk.

With varying competence in laboratory service, the proportion of high counts by communities is opened to much question. But our data would substantiate the general impression that all in all the larger the community the cleaner and safer the milk, because of better regulations, more competent inspection and more pasteurization.

The percentage of total milk solids and butter fat by population groups shows nothing striking.

There has been a most encouraging increase in the number of communities annually adopting regulations requiring that all milk be either pasteurized or from tuberculosis-free cattle. This has been most marked in the larger communities.

However, since there are still 30 per cent of our people who live in cities and towns which allow raw milk from tuberculous cattle to be sold, this movement against milk from tuberculous cattle must be expedited by state regulation.

NOTE: We are indebted to Helen Smith of the Department staff for valuable assistance in the preparation of the statistical tables.

Commonwealth of Massachusetts

THE State Department of Public Utilities has issued an order specifying the contents of first-aid packages to be carried by railroads.

The present order provides that every railroad corporation shall carry upon each engine or rail motor car and in a car of each passenger train and in the caboose car of each freight train at least one first aid package containing:

1. Four aseptic gauze pads for large wounds, $2\frac{3}{4}$ " by 3", made of 12 thicknesses of No. 1 A gauze, with a gauze bandage 2" wide and 60" long attached for fastening pad to wound, and with the pad sewed to the middle of the bandage.

2. Four aseptic gauze pads for small wounds, $1\frac{1}{2}$ " by 2", made of 12 thicknesses of No. 1 A gauze, with gauze bandage 1" wide and 18" long.

Said gauze pads and bandages to be contained in individual glassine envelopes, those containing small dressing to be marked "For Small Wounds" and those containing large dressings to be marked "For Large Wounds."

3. Four mercuric iodine applicators of a size not less than those contained in a packet marked "A" and dated July 25, 1930, on file with the railway and motor bus inspection division of the department.

4. One-quarter ounce of bicarbonate of soda and petrolatum for burns.

An Effective and Practical Definition of Pasteurization*

LESLIE C. FRANK, C. E., F. A. P. H. A.

Sanitary Engineer in Charge, Office of Milk Investigations, U. S. Public Health Service, Washington, D. C.

AN effective and practical definition of pasteurization should satisfy the following criterions:

1. It must be effective with respect to the killing of any pathogens in milk.
2. It must be practical with respect to its enforcement by the health official.
3. It must be practical with respect to its application by the dairy industry.

The 1929 issue of the *Standard Milk Ordinance and Standard Milk Control Code*, recommended to American municipalities by the U. S. Public Health Service, contains the following definition of pasteurization which it is believed satisfies the above criterions.

Pasteurization—The terms “pasteurization,” “pasteurized,” and similar terms shall be taken to refer to the process of heating every particle of milk or milk product to a temperature of not less than 142° F., and holding at such temperature for not less than 30 minutes in pasteurization apparatus approved by the health officer, provided that approval shall be limited to such apparatus which requires a combined holder and indicating thermometer temperature tolerance of not more than one and one-half degrees Fahrenheit (1½° F.), as shown by official test with suitable testing equipment, and provided that such apparatus shall be operated as directed by the health officer and so that the indicating thermometers and the recording thermometer charts both indicate a temperature of not less than 143½° F., continuously throughout the holding period, provided that nothing contained in this definition shall be construed as disbaring any other process which has been demonstrated as of at least equal efficiency and is approved by the state health authority.

It will assist in understanding why this definition satisfies the three criterions if we first examine it in detail and ascertain the reasons for each clause or phrase of which it is composed.

The first clause, namely, that “pasteurization . . . shall be taken to refer to the process of heating every particle of milk to 142° F. and holding at such temperature for not less than 30 minutes,” is the

* Read at a Joint Session of the Food, Drugs and Nutrition and Public Health Engineering Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 3, 1929.

"core" of the definition. It implies, of course, that a temperature of 142° F., if actually applied to every particle of milk for 30 minutes, will kill or render non-dangerous any milk-borne pathogens which may be present. It is believed that the majority of leading bacteriologists will concur in this assumption.

The second clause, "in pasteurization apparatus approved by the health officer," is included in the definition because failure to include it might lead to disagreement between health officers and pasteurization plant owners or pasteurization machinery manufacturers, as to whether a given type of pasteurization equipment is so designed as to be capable of reliably applying a temperature of 142° F. to every particle of its milk contents for 30 minutes. Some agency must have final authority to pass upon such questions and it is believed that the health officer is the proper agency.

It is suggested that the health officer's approval should be based in general upon whether the apparatus in question complies with the design specifications contained in the *Standard Milk Control Code* recommended by the U. S. Public Health Service, since this will have the advantage of promoting standardized design requirements; and in particular upon whether the apparatus meets the temperature tolerance provision of the next clause of the definition. Whether the apparatus complies with the first requirement may be ascertained by simple inspection of the apparatus itself, or its blue prints. Whether the apparatus complies with the second requirement can be determined only on the basis of records of actual official tests.

The third clause, "provided that approval shall be limited to such apparatus which requires a combined holder and indicating thermometer temperature tolerance of not more than $1\frac{1}{2}^{\circ}$ F.," is included in the definition because it has been determined by careful engineering tests of many types of pasteurization equipment that it is easily possible to design and construct pasteurization equipment which does not require a temperature tolerance greater than $1\frac{1}{2}^{\circ}$ F. The inclusion of this clause in the definition will support the health officer in resisting any pressure to induce him to accept a greater tolerance.

It may be advisable to explain for the lay reader the meaning of the term "temperature tolerance" as used in the definition. Explained in non-technical language, the phrase means that the health officer shall approve only apparatus which is so designed and constructed that when its indicating thermometer registers an "apparent" temperature of $143\frac{1}{2}^{\circ}$ F., the lowest actual temperature of any particle of milk in the system will be not less than 142° F. In other words, the temperature tolerance is the maximum difference allowed

between what the thermometer leads one to believe is the temperature of the coldest drop of milk and the actual temperature of the coldest drop.

The term "combined holder and indicating thermometer temperature tolerance" is used because the $1\frac{1}{2}^{\circ}$ F. tolerance is made up of an allowance of one degree for variations in actual temperature in the various corners and pockets of the holder system, plus a one-half degree allowance for deviations in the readings of individual satisfactory thermometers.

The fourth clause, "as shown by official tests with suitable testing equipment," is included in the definition in order to protect the health officer against any pressure to accept tests made by unofficial agencies such as the manufacturers, or private laboratories employed by the manufacturers, since in some cases such agencies might not be entirely unbiased.

"Official tests" should be interpreted to mean tests made by an official public health agency, that is, either by the city health department, the state health department, or by the U. S. Public Health Service. The term "suitable testing equipment" means testing equipment equal in performance to the thermocouple-potentiometer equipment used by the U. S. Public Health Service in its tests, with which it is possible to determine temperatures accurately in any portion of the holder system.

The fifth clause, "provided that such apparatus shall be operated as directed by the health officer," is included in the definition because even apparatus which is properly designed cannot be depended upon to pasteurize effectively unless properly operated.

Here again, just as in the case of design approval, it is recommended that the health officer's approval of the operation be based upon the provisions of the U. S. Public Health Service *Standard Milk Control Code*, since this will tend to promote standardization in operation requirements.

The details of both design and operation are incorporated in the *Standard Milk Control Code* rather than in the *Standard Ordinance* because their inclusion in the Ordinance would make this instrument unnecessarily long and greatly increase the cost of printing when enacted by municipalities. As it is, some small municipalities object to the present printing cost.

The sixth clause, "and so that the indicating thermometers and the recording thermometer charts both indicate a temperature of not less than $143\frac{1}{2}^{\circ}$ F. continuously throughout the holding period," is incorporated in the definition in order to insure that even the coldest

particle of milk in the apparatus will have been held for 30 minutes at an actual temperature of at least 142° F. This will be true if the indicating thermometer indicates an "apparent" temperature of $143\frac{1}{2}^{\circ}$ F. since the maximum temperature tolerance previously allowed in the design was fixed at $1\frac{1}{2}^{\circ}$ F., and therefore the maximum temperature deviation in the system will be $1\frac{1}{2}^{\circ}$ F. or less.

Not only the indicating thermometer, but also the recording thermometer chart, must show the required temperature for the full holding period, so that the health officer may assure himself that the required temperature is maintained for the proper length of time, not only when the inspector is present but also between inspections.

The question may be asked: What is to prevent the pasteurization plant from setting the recording thermometer so as to read a higher temperature than the indicating thermometer and thus delude the health officer?

The answer is that one of the detailed operation requirements given in the *Standard Milk Control Code* reads as follows:

The setting of recording thermometers shall be checked against the indicating thermometers daily by the plant operator and at least bi-weekly by the health officer, and shall be kept adjusted so as at no time to read higher than the indicating thermometer.

It will be apparent that the enforcement of the above requirement would soon result in the discovery by the health officer of any attempt to defraud by incorrectly setting the recording thermometer.

The seventh clause in the definition, "provided that nothing contained in this definition shall be construed as disbaring any other process which has been demonstrated as of at least equal efficiency, and is approved by the state health authority," has been included in the definition in order to prevent the definition from discouraging attempts to develop new and improved methods of pasteurization. It is conceivable, for example, that effective and practical methods of applying higher temperatures and shorter exposures may be developed and generally accepted by health authorities in the future. Unless this clause were included in the definition, it would be necessary to reword the definition in order to make the acceptance of such a method by the health officer legal. With the clause included it will be legal for any state health officer to admit other methods of pasteurization which may be demonstrated to him to be effective. As soon as such acceptance is general, the detailed requirements of the new method may be included in the definition.

Having now discussed the details of the definition of pasteuriza-

tion we may discuss the reasons the definition satisfies the three criterions previously given, namely:

1. That it is effective with respect to the killing of milk-borne pathogens.
2. That it is practical with respect to its enforcement by the health officer.
3. That it is practical with respect to its application by the dairy industry.

That the definition is effective with respect to the killing of milk-borne pathogens will have been clear from the detailed discussion already given.

That the definition is practical with respect to its enforcement by the health officer will be apparent when it is pointed out that the officer's duties are principally limited to the following:

1. He or his inspector must examine every pasteurization apparatus in use in the plants in his city and check the design characteristics against the design requirements listed in the *Standard Milk Control Code* with respect to thermometers, inlet and outlet valves, foam heating devices, vat and pocket covers, and holding time in the case of apparatus in which the holding time is automatically controlled.

2. He or his inspector must approve only such apparatus as meets these requirements and which has been found by his own tests or by those of the state health department or of the U. S. Public Health Service to show a deviation in temperature between the hottest and coldest particles of milk of not more than one degree Fahrenheit. (The U. S. Public Health Service is now preparing reports of tests on all widely used pasteurization apparatus.)

3. The indicating thermometer used must be checked against a standardized thermometer and show a deviation therefrom of not more than one-half degree Fahrenheit between 142° F. and 145° F.

4. The operation of each pasteurization apparatus must be inspected to see that it complies with the requirements listed in the *Standard Milk Control Code* as follows: (a) routine checking of the recording thermometers against the indicating thermometers; (b) the routine checking of the recording thermometer charts to see that none of the holding period sections of the curves shows a recorded temperature of less than 143½° F., and to see that each chart has inscribed upon it the reading of the indicating thermometer during a holding period, and the time at which the reading was taken; (c) the occasional inspection of all single vat installations which are not provided with leak protector valves to see that they are disconnected from the raw milk supply and from the outlet piping during the times required by the code; (d) the disinfection of outlet valves immediately prior to the discharge of pasteurized milk; (e) the proper use of foam heating devices; (f) the keeping closed of all vat and pocket covers during operation; (g) the pre-heating of all holders to at least the pasteurization temperature when required by the code.

It is believed that it is reasonable to state, therefore, that the "definition of pasteurization in the 1929 *Standard Ordinance and Code* is practical with respect to its enforcement by the health officer."

Finally, it is believed that the definition is practical with respect to its application by the dairy industry, because there is no requirement connected with it which is not easy to apply. Many pasteuriza-

tion plants located in cities enforcing the *Standard Milk Ordinance* are complying with the definition without difficulty. Furthermore, the principal objection to many present pasteurization definitions in the eyes of the industry has been avoided, namely the matter of cream line damage. There is no danger of damaging the cream line if the definition is intelligently applied by the pasteurization plant operator.

DISCUSSION

The Practical Aspects Concerned with Securing Enforcement of Suggested Definition for Pasteurization

GEORGE W. GRIM, V. M. D., F. A. P. H. A.

Milk Control Officer, Milk Control District No. 1, Ardmore, Pa.

THE proposed definition for pasteurization suggests a minimum heat treatment (142° F. for 30 min.) to which every particle of milk must be subjected. It establishes a temperature tolerance of 1° F. to allow for what are described as reasonable variations in the milk when processed commercially in apparatus of approved type. An additional tolerance of $\frac{1}{2}^{\circ}$ F. is established for acceptable inaccuracies of indicating thermometers. It is contemplated that the combined temperature tolerance of $1\frac{1}{2}^{\circ}$ F. be added to the 142° F. minimum, operation to be of a character to insure that the indicating thermometer and the recording thermometer charts both show not less than $143\frac{1}{2}^{\circ}$ F. continuously throughout the holding period.

Granted such operation, the control official is to assume that no particle of milk undergoing treatment will fall below 142° F. at any time during the 30-minute holding period; provided the process has been carried out in apparatus approved by the health officer and that such apparatus shall be operated as the health officer may direct.

The terms of the definition restrict the health officer from approving commercial pasteurizing apparatus in which the combined holder and indicating thermometer temperature variation is more than $1\frac{1}{2}^{\circ}$ F. Temperature tolerances have been provided for recognized variations in the temperature of heated milk during the required holding period, resulting from imperfections inherent in apparatus of approved type, also for recognized inaccuracies of indicating thermometers, but not for recognized temperature variations always occurring during the course of ordinary milk plant operation, the result of reasonable and unavoidable deviations from any established procedure which the operator may endeavor to follow in the practical operation of commercial pasteurizing apparatus.

Safety margins, contained in pasteurizing definitions enforced during the past decade, were imposed, not primarily for the purpose of compensating for recognized defects current in pasteurizing apparatus, or for the purpose of compensating for inaccuracies of indicating thermometers, not required; but chiefly, for the purpose of compensating for recognized variations in the heat treatment of milk resulting from operation approximations of commercial practice. The proposed definition, while expressly recognizing the need for proper operation, fails to recognize any

need for this margin of safety. Accordingly, the health officer must expect to secure 100 per cent compliance upon the part of the milk plant in operating the pasteurizer as he may direct.

One must at once be impressed by the many new responsibilities to be assumed by the control official in the matter of pasteurizing equipment, particularly in the matter of the health officer placing his stamp of approval on the different pasteurizer designs, also the assumed responsibility of specifying precisely how apparatus should be operated to obtain a fixed result.

It would seem entirely agreeable to accept the proposed minimum heat treatment as effective for the destruction of milk-borne pathogens if actually applied to every particle of milk. To be effective, however, pasteurization must be conducted in proper apparatus under proper control. To be practical with respect to their application, the requirements must be such that the operator can carry them out in the course of ordinary milk plant operation.

To insure enforcement of that portion of the suggested definition which deals with approved apparatus it has been recommended that the control official's approval be based upon the design specifications prescribed in the *U. S. Standard Milk Code*. For the purpose of discussion let us assume that a certain pasteurizer has satisfied these design specifications. The health officer is then to place his approval upon the pasteurizer and permit its use, provided it is operated as directed by the control official. It now becomes the task of the health officer to direct the operation of the apparatus which he has approved in such manner that the variation in temperature between the hottest and coldest particles of milk undergoing treatment will never be greater than 1° F. In order that this requirement may be easily carried out by the control official he is again referred to the *Code* from which he is supposed to obtain information sufficient to direct the proper operation of a given design.

While it is contemplated that pasteurization shall be carried on only in apparatus of approved design, does it of necessity follow that such apparatus, when operated so that the recording thermometer charts indicate a temperature of not less than $143\frac{1}{2}^{\circ}$ F. continuously throughout the holding period, actually applies at least 142° F. for at least 30 minutes to every particle of milk?

Assuming that apparatus approved upon the basis of the specifications of the *Code* has been operated as recommended—is the health officer justified in accepting a temperature tolerance of $1\frac{1}{2}^{\circ}$ F. as sufficient to insure the heating of every particle of milk to at least 142° F. for 30 minutes?

Whether effective pasteurization would result from the application in the field of the suggested definition, and whether the definition is practical with respect to its enforcement by the health official and with respect to its application by the dairy industry, are questions which must be answered—from our experiences in the supervision of the pasteurization process, from an examination of apparatus now in use in the majority of our plants, and from an examination of the design and operating specifications of the *Standard Milk Code* which the U. S. Public Health Service recommends to health officers for use as a text in approving and directing the operation of the various pasteurizers.

Under "Design specifications to be met in order to secure health officer's approval" we find rather specific instructions concerning acceptable locations for the various types of thermometers required on pasteurizing apparatus. Much space is given to specifications to be followed by manufacturers in the construction of thermometers for use by the dairy industry and the control official. With slight ex-

ceptions, the only references in the *Code* concerning design specifications of the pasteurizer which the health officer is to approve concern themselves with the character of valves through which the milk enters or discharges, and the pasteurizer lids or covers.

Aside from the requirement that reasonably accurate and easily readable thermometers be used to indicate and record the temperature of milk undergoing treatment, the thermometer specifications have little value other than tending to standardize types of thermometers used for pasteurization. On the other hand, the design specifications, if followed by the health officer, would result in his approving of the use of apparatus not designed to furnish a record of the full heat treatment applied to the milk. Strict interpretation of present pasteurization definitions does not permit the operation of apparatus without recording upon a chart the full heat treatment applied. While most health departments have in the past failed to enforce the provisions relating to temperature records of milk in holders supplied at the pasteurizing temperature, it is considered entirely practical to obtain such records in every design of pasteurizer now in use, with the possible exception of one. Therefore, with respect to location of thermometers the control official should consider the design specifications applicable to vat, pocket or continuous flow installations into which milk passes at pasteurization temperature inadequate, because they fail to require any record of the full heat treatment applied in three of the four types of equipment mentioned in the *Code*, namely vat, pocket and continuous flow, into which milk passes at pasteurizing temperature. The control official should most emphatically refuse to approve any and all designs of apparatus not equipped to furnish a satisfactory record of the full heat treatment applied in an endeavor to effect pasteurization.

A record of the full heat treatment applied in holders supplied at the pasteurizing temperature is essential to the control official for the following reasons:

1. To aid in determining whether each pocket of holder was pre-heated to at least the pasteurizing temperature immediately before the milk was passed into the apparatus.
2. To indicate effectiveness of device for heating air in holder above the milk.
3. To show cold air leakage into holder particularly during interval between emptying and filling.
4. To record holding time and temperature of milk in each individual pocket of holder. (Temperature reductions occasionally occur during unavoidable shut-downs in milk plant operation. Were the control official to base his approval of apparatus on the design specifications recommended by the U. S. Public Health Service *Milk Code* there would be no record of supposedly pasteurized milk that had fallen below the minimum temperature from some cause and which had been raised to the pasteurizing temperature in the holder just before the operator permitted it to pass over the thermometer bulb located in the outlet manifold.)
5. To record variations in temperature of milk in pockets caused by variations in temperature of water used in maintaining temperature of apparatus.
6. To comply with paragraph I, Item B of suggested code: "The pasteurization equipment shall be operated so that the indicating thermometer and the recording thermometer charts both read at least the temperature which the definition of pasteurization requires the thermometers to show continuously through the holding period."

The specifications concerning location of thermometer fittings "to conform to that of standard International Association Milk Dealers wall type fitting" should

be objected to. Why should the International Association of Milk Dealers be authorized by the health department to designate location of seat of indicating thermometer in "batch type pasteurizer"?

MAINTAINING MINIMUM HOLDING PERIOD

The design specification in the *Code* under the above heading would specifically authorize the dairy industry to operate holders equipped with automatic, controlled effluent and affluent valves in such a way that the control official would have absolutely no record of the time period the milk was held, its temperature during the holding period or the interval of lapsed time between the opening and closing of such automatic valves.

In lieu of recorded holding time the *Code* suggests that the control official accept certain design and operation conditions which he may prescribe and require in the case of automatically timed pocket type or continuous flow holders. In my opinion it is just as essential to have a full record of the heat treatment applied to milk passing through a continuous flow holder as it is to have a similar record for a single manually operated vat installation. In the case of the manually operated vat the *Code* demands a record and goes into detail to explain how the control official should read the chart in order to approximate the holding time applied. In the case of the flow holder the *Code* merely requires that the control official test the holder when installed, following repairs or alterations, see that it has an apparent holding time of 31 minutes, and satisfy himself that its construction and operation will insure proper holding of the milk. I am amazed that such a procedure should be considered adequate and that having followed it, health officers of this country should be urged to approve apparatus of this type. Almost while your back is turned the operator can increase the rate of flow of milk through such holders more than 30 per cent with no record left of his manipulations. That such increases in rate of flow are common in the operation of milk plants at present may be illustrated upon charts made by a speed recorder installed upon a milk pump supplying milk to a continuous flow holder. Figure I illustrates that during a single day's run three changes were made of a small pinion gear resulting in increasing the speed of the pump supplying milk to the holder to a point considered well beyond the legal holding capacity of the apparatus.

The control official will do well to consider any pasteurizer not equipped to give a record from which he may at least approximate the minimum holding period of milk undergoing treatment potentially dangerous and beyond the scope of his control. Therefore, before any serious consideration should be given to the matter of accepting even tentatively a holder of the flow type proper records to indicate the rate of operation should be demanded and obtained by the control official. It is entirely practical to make such records in the course of milk plant operation. I would refuse in the interests of the milk consuming public either to approve or to accept pasteurizing equipment meeting fully the design specifications of the *Code* as they apply to holders of this type.

In the case of automatically operated valves of pocket type holders a record of opening and closing of the valves should be required before acceptance is granted.

INLET AND OUTLET VALVES

The design specifications of the *Code* recommend the acceptance of valves with pockets and suggest overcoming this defect by continuous steaming. The control

FIGURE I—Reproduction of graph made by speed recorder designed to record rate of operation. The graph indicates three recorded increases in speed of pump supplying milk to holder. The increases in speed of the milk pump have been produced by changing a pinion gear attached to the shaft of the motor driving the pump. By replacing one pinion gear with another the presumed 30-minute holding period is materially shortened. The graph made by the pen falling toward the center of the chart evidences the frequency and duration of shutdowns occurring during the course of a single day's operation. Except for a few isolated instances, recording devices capable of making records, as shown in Figure I, have not been used as an aid in controlling the pasteurizing process.

official should refuse to accept such non-flush type valves because experience has already proved the requirement for continuous or automatic steaming not practical with respect to its application by the dairy industry. Steam pressures, particularly in small plants, where such valves are most frequently met with, are subject to extreme variation and cannot, under the varied conditions of milk plant operation, be depended upon to keep milk contained in such pockets at the pasteurization temperature. It is entirely practical for the industry to supply pasteurizers with valves which do not have to be steamed continuously. The operating specifications relative to valves require automatic steaming of valves, just prior to the discharge of

milk, in all types except single vat installations. From my own experience and observation in cities reputed to have succeeded in eliminating defects current in pasteurization apparatus I am convinced that attempts at automatic steaming of valves have in many instances resulted in failures even to heat the valve which was supposed to be automatically steamed. The problem of water-logged steam lines, resulting from steam trap and boiler deficiencies, has rendered many attempts at automatic steaming wholly worthless. Therefore I would recommend that the health officer refrain from considering satisfactory past effort to sterilize outlet valves by automatic steaming. The manufacturers should be urged to provide more dependable methods for accomplishing the desired result. For the present disconnecting the outlet valve and sterilizing by heat manually appears most dependable.

FOAM HEATING

In order that any differences between the temperature of foam and that of milk beneath might be kept within the 1° F. tolerance established for the apparatus by the definition, the *Code* provides that if foam is present the atmosphere above milk shall be kept at pasteurization temperature. Exactly how the health officer is to accomplish this is not clear. The admission of steam into the air space beneath the lids is suggested. There is a statement about using a steam trap properly designed to avoid the discharge of water into the milk. So far as I have been able to learn all steam traps are so designed, but none that I have ever used or observed avoided the discharge of water into the milk at certain times during the varied conditions which present themselves in the usual course of milk plant operation. It is difficult to understand how this feature of the foam heating problem could be classed by Mr. Frank in the category of requirements "easy to apply."

I have often tried to heat foam and to maintain proper pasteurization temperature in it. Foam may occur at any time in any type of holder, so all types must be designed to cope with it. Milk foam is an extremely peculiar and elusive substance. At one season there may be none; at another much. Today it may be low and fine in texture, tomorrow upstanding and coarse. I have never succeeded in maintaining foam temperatures at a point equal to the milk throughout the day's run. I consider satisfactory heating of foam the most difficult problem to overcome in eliminating defects of pasteurization apparatus. Certainly we have not yet progressed to the point where every particle of foam in the various types of apparatus, entitled to approval under the design specifications of the *Code*, is maintained at a minimum of 142° F. when the indicating thermometer indicates 143½° F. On the contrary, the practical application of pasteurization commercially even in plants of the better type is such that foam temperatures are frequently 10 or 15° F. below those of the milk as indicated by the recording thermometer. From a practical standpoint it might be stated that efforts to maintain satisfactory temperature of foam have not yet commenced. Except for an extremely small number of large automatic vat or pocket type holders of modern design, practically no effort is being made by pasteurizing plants either to heat foam or maintain the temperature of the air above the milk at a point equal to the milk. Therefore, data are not yet available upon which to base a conclusion that a definition for pasteurization which establishes a temperature tolerance of but 1° F. and exacts 100 per cent compliance in adhering to operating directions is practicable either with respect to its enforcement by the health officer or its application by the dairy industry.

VAT OR POCKET COVERS

The *Code* sets forth design specifications calculated to prevent anything from falling into the vat in either the open or closed position. It appears that an important point has been overlooked here—that of requiring the lids to be “tight fitting and properly insulated.”

PREHEATING OF HOLDERS

The *Code* is not clear concerning how preheating is to be accomplished. Many holders are not provided with independent means of temperature maintenance. Vat or pocket type pasteurizers are frequently insulated with cork and unless sufficient heat is supplied to such apparatus at the commencement of the day's run, temperature balance of the holder will not be acquired from the heat supplied to the milk. This fact is recognized by the *Code*, which suggests as a remedy the heating of the apparatus by steam or otherwise before the holding period begins. I do not consider it either proper or safe to accept or approve any holder which receives the milk at the pasteurization temperature unless such holder is so constructed that the temperature of the pockets can be brought to the pasteurization temperature—and that such fact be registered upon recording thermometers installed upon each pocket—before the heated milk is passed into them. If satisfactory temperatures cannot be obtained before the milk enters, final heating should be effected in the holder. I should also require in this type of holder that means be provided in each pocket to raise the temperature of the milk in the event of mishaps, such as heater failure or shutdowns, resulting in milk falling below pasteurization temperature.

OPERATION SPECIFICATIONS

One of the most notable requirements of the proposed definition is the clause, “provided that such apparatus shall be operated as directed by the health officer.” Mr. Frank suggests that the health officer's approval of operation be based upon the provisions of the U. S. Public Health Service *Standard Milk Code*. Design approval is limited to apparatus which requires a holding temperature tolerance of not more than 1° F. How is the control official to direct such operations? The *Code* does not begin to tell him how to operate commercial apparatus so that temperature variations during operation, day after day, will be not more than 1°. In the practical application of heat to milk under commercial conditions we simply do not have plants capable of sustained operation within the narrow limits of 1° F., and neither this nor any other definition for pasteurization will provide them.

The best that can be hoped for is to select, after careful study has been made of the various types of equipment, under the varied conditions of milk plant operation, some reasonable temperature margin to be added to a temperature margin necessitated by unavoidable variations resulting both from imperfections in thermometers and apparatus, the sum to represent a safety margin necessary to compensate for the uncontrollable and varied fluctuation in ordinary milk plant practice. That Mr. Frank himself realized this is clear from a paper he presented at the Buffalo meeting of this Association: “That a proper definition of pasteurization will be one which applies to every particle of milk pasteurized and which requires in addition a margin of safety for the design and operation approximations of commercial practice.”

I submit that absolutely no margin of safety to cover operation approximation of commercial practice has been included in the definition suggested here.

I submit further that commercial pasteurization plants of the present day cannot begin to operate within the narrow limits of 1° F. as a maximum under the varied conditions they are called upon to meet.

The conclusion drawn that the suggested definition for pasteurization is practical with respect to its enforcement by health officers and with respect to its application by the dairy industry is without a sound basis and misleading.

It has not been shown by data or otherwise that a combined temperature and indicating thermometer tolerance of $1\frac{1}{2}^{\circ}$ F. will insure the heating of every particle of milk to at least 142° F. in the various described approved designs of pasteurizing apparatus, nor that ordinary commercial pasteurizing apparatus can be successfully operated within the range of the tolerance suggested.

It has not been shown that the requirements exacted by the proposed definition are practical with respect to their application by the dairy industry, nor their enforcement by the health official, nor that they are *easy to apply*.

A proper definition of pasteurization will be one that provides a satisfactory margin of safety to compensate for reasonable design imperfections of apparatus, inaccuracies of thermometers and for reasonable and unavoidable variations resulting from operating approximations of commercial practice. An extensive study of the variable conditions in average milk plants likely to affect operation of the various types of pasteurizing apparatus is necessary to establish a basis for a temperature margin to compensate for reasonable operating approximations of commercial practice. Extensive studies, with the publication of data showing temperature variations of milk, foam and air in the various designs of pasteurizing apparatus are necessary for the same reason. Pending the publication and acceptance of results of such studies it is suggested that the health officials require that milk sold as pasteurized be heated for 30 minutes at a temperature of 145° F.

CLOSING REMARKS

LESLIE C. FRANK, C. E.

IT should be noted that Dr. Grim's criticisms are directed largely at the design and operation specifications for pasteurization machinery contained in the *Standard Milk Control Code*, rather than at the definition of pasteurization itself.

1. The only one of Dr. Grim's criticisms which is directed at the definition itself is that it does not contain an adequate margin of safety to cover design and operation deviations of commercial practice.

The margin of safety embodied in the definition is the difference between the required temperature of $143\frac{1}{2}^{\circ}$ F. and the lethal limit for milk-borne pathogens. Most authorities agree upon 140° F. as the lethal limit when a time of 30 minutes is used. One and one-half degrees of the $3\frac{1}{2}^{\circ}$ margin is intended by the definition as a *design* tolerance, and the definition requires that the health officer shall not approve any apparatus which shows a temperature deviation greater than $1\frac{1}{2}^{\circ}$ when properly operated. The researches of the U. S. Public Health Service indicate that properly designed machinery can easily meet this requirement.

As to an *operation* margin or tolerance I have come to the conclusion that such a tolerance is illogical and dangerous. Every plant should be required to comply strictly with the $143\frac{1}{2}^{\circ}$ F. minimum, all operation deviations to be *above* this temperature, and the plant should be punished by de-grading or revocation of permit whenever it fails to comply. Dr. Grim suggests 145° F., and it is assumed that he means this temperature to be one at which the operator will *aim*, and *above and*

below which the operation deviations will occur. As a matter of fact, a definition of $143\frac{1}{2}^{\circ}$ F. which is rigidly enforced as a *minimum* will result in a higher actual temperature than a definition of 145° F. which is *aimed at* by the operator, but which is deliberately assumed to allow for operation deviations of unknown magnitude.

As before stated, Dr. Grim's remaining criticisms deal with the machinery specifications and not with the definition. They are very briefly discussed below:

2. Dr. Grim objects to the fact that the *Standard Milk Control Code* does not require any record of the holding time in automatically timed holders. He states that this would make it possible for the plant operator to delude the health officer by changing a pinion gear, for example, in order to change the time. May I point out that no definition, not even the 145° F. definition suggested by Dr. Grim, will prevent fraud. Fraud must be overcome by inspection and by a proper, wholesome relationship between the inspector and the plant. It cannot be overcome by changes in the definition or in the specifications. If properly designed, automatically timed pasteurizers are not fraudulently tampered with, the milk will automatically and dependably be held for the proper time. The addition of time recorders will merely result in transferring the fraudulent intent from the pinion gear to the time recorder.

3. Dr. Grim further objects to the fact that the *Standard Milk Control Code* does not require flush type valves where the outlet valves are coupled close to the holder and continuously heated. He criticizes the practice of valve steaming because he has noted imperfect compliance in several instances. It is emphasized that the faulty instances he reports should not be permitted to discredit successful practice. There is no sound engineering reason why steam cannot be forced continuously through a steam port in a valve.

4. Dr. Grim's third criticism is that the *Code* requires automatically operated valves to be disinfected automatically, which he disapproves. He states that he has observed several instances of improper compliance with this requirement. Here again there is no sound engineering reason why steam cannot be automatically admitted to valves which open and close automatically and we should not allow ourselves to be misled into changing this item merely because certain plants have been observed to be improperly carrying it out.

5. Dr. Grim further criticizes the *Standard Milk Control Code* because he believes its requirement that the air above the milk surfaces shall be kept at or above the pasteurization temperature in order that any milk foam may be kept at or above the pasteurization temperature, cannot be accomplished, and that when it is attempted to heat the air by admitting live steam, water of condensation will be added to the milk, to which he objects.

The U. S. Public Health Service has experimented with several methods of heating the air above the foam. It has been impossible to secure satisfactory results by dry-heating the air, but the admission of wet steam directly to the air itself has given satisfactory results. It is possible that the unsuccessful results reported by Dr. Grim were in connection with attempts to use the dry-air method. His objections to the use of steam on the score that water of condensation will enter the milk is not considered sound. Even if the water trap were to fail utterly the result would only be a fraction of a thimblefull of water of condensation to each pint of milk. The sensible milk consumer would immediately prefer this negligible amount of water of condensation to the alternative of improper pasteurization.

6. Dr. Grim objects that the *Code* does not require the covers of vats and pockets to be insulated. The September, 1929, issue of the *Code*, which appeared several weeks before his discussion, makes this requirement.

7. Dr. Grim's objection that the covers are not required to be tight-fitting is considered to be indefinite. A requirement of hermetic sealing would be impracticable and it would seem that any other interpretation of "tight fitting" is satisfied by the requirement of the *Code* that the covers of vats be so constructed that nothing on top thereof will drop into the vat in either its open or closed position and that the covers of all equipment must be insulated and kept closed except in case of emergency.

8. Dr. Grim considers inadequate the requirement of the *Code* that certain types of holders shall be pre-heated with steam or otherwise so that the metal shall be at least at the pasteurization temperature before the holding period begins, because the requirement does not state how such pre-heating shall be accomplished. It is certain that it *can* be accomplished inasmuch as it is done every time the apparatus is sterilized by means of heat. It is believed that the *exact* method selected should be left to the operator.

9. Dr. Grim's next objection to the *Standard Milk Control Code* is that it does not require independent recording thermometers for each pocket of multiple pocket holders. He deems these necessary in order that a record may be had of the fact that the holder has been pre-heated. The *Code* now requires a recording thermometer in the outlet piping to which all of the pockets feed, and if pre-heating is not properly done the first milk temperature shown by the outlet recorder will be less than the required temperature, which will be sufficient evidence.

10. Dr. Grim's next objection is that the *Standard Milk Control Code* does not require each pocket to be equipped with independent heating means, which he thinks should be provided in order to prevent inadequately heated milk from reaching the cooler following heater failures or shut-downs. This is considered an unnecessarily complicated means of achieving an object which can be achieved by any one of three methods, an example of which is the automatic return-flow valve, which is more positive than Dr. Grim's suggestion. It should be noted that the object itself, which it is desired to achieve, is made mandatory by the *Code*.

FOUR WEEKS TO GET A NEW MEMBER!

SEPTEMBER 15 TO OCTOBER 13

During four weeks, September 15–October 13, members of the A. P. H. A. are being offered the opportunity to help strengthen their Association by bringing in new members.

Members joining during this drive will receive the magazine free during November and December.

The names of those who send in one new member each will be posted at the Fort Worth meeting and printed in the American Journal of Public Health. Those sending in more than one member will receive special mention.

What are you doing to coöperate with the Association in this effort?

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

EDITORIAL COMMITTEE

COMMERCIAL COOPERATION AND PUBLIC HEALTH

ONE of the opportunities easily available to health workers and of which too few take advantage is the coöperation that ethical commercial organizations offer for the furtherance of their public health programs.

Some of the best pieces of health education work in the United States are being done by commercial concerns. Many of them maintain expensive laboratories, in charge of scientists of high standing, which are constantly experimenting and adding to our knowledge of nutrition, milk sanitation, water purification, communicable disease control, and all of the branches of sanitary science.

There is hardly a problem that can be brought forth that some commercial house of sound reputation has not worked on and produced results, if not conclusive, at least suggestive.

Delegates to the Fort Worth Annual Meeting of the American Public Health Association will see an exhibit there in which fifty or more such organizations are participating. There is much to see and to learn in that exhibit. Their annual appearances at meetings of the American Public Health Association are regarded by most houses as the time to present new products, new services, new discoveries. The men and women in charge of the exhibits are trained workers, many of them recruited from the professional public health field and Association members of long standing. From the background of their own experience, they know public health and the application to it of the equipment and products they are exhibiting.

Every delegate to Fort Worth should plan his schedule so that

ample time is provided to study the exhibits and to make the acquaintance of the exhibitors. It would be wise to miss a paper now and then if necessary. This first-hand knowledge of what commercial organizations are doing to make our work easier or more effective will be valuable out of all proportion to the time spent in acquiring it.

GLUCOSE ("CORN SUGAR," SO-CALLED) IN FOODS UNDECLARED ON LABELS

THE recent attempts of certain interests to break down the effective enforcement of pure food laws by legislation in Congress having completely failed, these interests are again resorting to measures that smack of insincerity. This time it is the plan to accomplish their object by an administrative decision from the Secretary of Agriculture, in the guise of an economic farm relief measure.

The manufacturers of prepared foods have found great inspiration in the enforcement of the food and drug laws. The purposes of such laws are primarily to protect the interests of consumers, and, in their interest, to prevent deception and fraud in the sale of food.

The enforcement of food laws has resulted in a greatly increased consumers' confidence in the prepared foods shipped in interstate commerce and sold in our markets. The laws forbid, among other things, the labeling of foods in a manner whereby consumers may be deceived.

It has always been held that any added sweetness imparted to foods, in their manufacture, is understood by consumers to be due to sucrose (common sugar), and that any substitute used in the place of sucrose should be declared on the label.

Corn sugar is recognized as a wholesome product and its use in the manufacture of foods is now permitted, and has always been permitted, when used in such a manner that it would not work deception on the consumer.

However, corn sugar is distinctly different from sucrose. It is much less soluble; it is only about half as sweet; and it has distinctly different properties from those of sucrose when used in the manufacture of many foods.

In recent years we have learned much of the value of broadcasting facts concerning the diet in preventing deficiency diseases and thus promoting public health. Prepared foods make seasonal products available throughout the year and their effect in broadening the diet cannot be overestimated. Any decision which would weaken public confidence in prepared food would undoubtedly reduce consumption of such foods.

In recent years the manufacturers of this product have sought to influence the agricultural interests of the west by claiming that corn sugar is equally as suitable as cane or beet sugar in the manufacture of foods and might largely, or perhaps entirely, replace common sugar for this purpose. They have made exaggerated statements regarding the amount of corn sugar that might be used in foods and the amount of corn that might therefore be consumed in its manufacture.

This question is not a new one. It is merely another phase of the glucose or corn syrup question which has been before Congress and departments from the time the food and drugs act was passed.

The corn products manufacturers, who alone desire this change, opposed the enactment of the food and drugs act and since that time have sought by every means within their power to have their products used in a way that would deceive consumers.

The food laws of the country today are not economic measures, and should not be considered in that light. They are consumers' measures that simply inspire honest manufacture, fair trade and a square deal to the consumer.

This entering wedge in the pure food law, that would pave the way for all kinds of rulings or legislation that would, in the end, make possible wholesale adulteration and bring back the disgraceful condition that existed prior to 1906, should not be permitted.

Corn sugar, so-called, if all that its proponents claim for it, should be unafraid of making its presence known on labels.

The consumers' present confidence in food law requirement should be continued rather than substitute a policy of "Let the Buyer Beware."

THE LÜBECK AFFAIR

DURING April, 1930, some 246 infants were vaccinated with BCG, the stock cultures of which are said to have been bought in Paris and the sub-cultures made by Dr. Deycke of Lübeck, an experienced immunologist. Fifty of the children soon became severely ill with enlarged inguinal and abdominal glands and showed other symptoms of acute tuberculosis. At present, according to the latest figures available, 46 deaths have occurred while 68 children are gravely ill. Criminal proceedings have been instituted against the medical director of the Lübeck Health Office and the chief physicians of the State Hospital and the Children's Hospital.

This deplorable disaster has raised a number of questions and will doubtless give material for the antis to work on. The German health office has sent Professor Lange to investigate, while Professor Dryer

and Captain Douglas have been sent by the Medical Research Council from England. Unquestionably other investigations will also be made. Professor Calmette states correctly that no such accidents have followed the extensive use of BCG in France and other countries.

The vaccine has been studied by many bacteriologists and clinicians, and the general opinion is that it is innocuous and cannot produce active tuberculous lesions. Upon the other hand, two American workers, Petroff of the Saranac Lake Laboratory, and Watson of Canada, have found that it does sometimes cause tuberculous changes. Petroff, by the method of dissociation, was able to separate the vaccine into two types, one of which was virulent for guinea pigs while the other produced lesions which healed. Others have failed to confirm these results. Under Park, of New York, the vaccine has been used with apparently excellent results. It will be remembered that the late Dr. Trudeau held that a living culture was necessary to produce immunity against tuberculosis, and he was followed in this belief by many others. In recent years the trend has been toward killed organisms for all vaccines and ample experience has demonstrated the success of this method in such diseases as plague and typhoid fever.

Whatever may have been the cause of the illnesses and deaths in the Lübeck case it should not deter us from further studies of immunization against tuberculosis. A scourge which destroys so many lives annually in practically every part of the world demands our utmost endeavors. No one would think of abandoning the use of morphine, for example, because it has often produced death. Without doubt, the cause of the accident will be determined by the investigations under way, and the use of this vaccine, or some other, will be made safer on account of the studies brought about by this accident.

However, it must always be borne in mind that the manufacture of biological products requires the highest technical skill, and their administration should be always by, or under the direct supervision of, physicians. In the Lübeck case, it is said that the vaccine was given outside of the hospitals and by midwives.

THE EPIDEMIOLOGY OF TYPHUS

THE recent report by Dr. William Fletcher¹ of his researches into the nature of typhus-like diseases that occur in the Malay States has stirred up again the controversy of how typhus fever may be distinguished as a pathological and epidemiological entity. It is rather surprising to note Dr. Fletcher's insistence that a fever must not be called "typhus"—"the public will not allow these diseases to be called typhus"—because quarantine is unnecessary.

It is surely admitted that the real quarantine in the case of European *Typhus exanthematicus* is directed more against the louse than against the virus of typhus itself. It is at least doubtful whether the "sanitary cordon" drawn around Poland after the war was as important as the habits of cleanliness of the people living on this side of the frontier in preventing the development of a pandemic of typhus fever.

If a disease is carried by different vectors in different parts of the world, does it thereby become a different disease either pathologically or epidemiologically? Surely not! Neither should the mildness of the attack in sporadic cases of "typhus-like diseases" excuse them from being called "typhus."

A recently published letter of the Health Commissioner of Virginia¹ states that there were in 1929 21 cases of "typhus fever" in the State of Virginia, most of them quite severe and 7 of them fatal. The attempt to label smallpox as "alastrim" did not prevent it, either, from reverting occasionally to its virulent form.

Maxcy and Mooser have shown that the virus from endemic typhus can be propagated in the louse and that, under these circumstances, *R. prowazeki* appear in the guts of these insects. This evidence, coupled with the evidence for the development of cross-immunity in animals, fully justifies Williams in speaking of the sporadic form of the disease in his state frankly as typhus fever.

It is perhaps not without significance that endemic typhus is not reported from the Mountain states, and that on the other hand a disease that is clinically and pathologically indistinguishable from typhus is reported from this region. It is true that the vector *Dermacentor Andersoni*, the Rocky Mountain tick, is not associated with typhus in other parts of the world. Again we would emphasize that a disease is not characterized by its vector. If ticks were as abundant upon the bodies of Coloradans as lice are upon the peasants of Russia, Rocky Mountain fever would almost certainly become an epidemic disease. In the meantime the same methods of experimentation may be applied here as in the case of the endemic typhus of the South. Not only the frank exanthematic form should be investigated, but also those milder forms recently described by Becker² in which a positive Weil-Felix test is found but no exanthem. If and when the evidence is as effective as is now the case for Brill's disease, the name "Rocky Mountain fever" should be discontinued and typhus should reign in its stead.

THE PUBLIC HEALTH DEPARTMENT IN MEXICO CITY

F. P. MIRANDA, M. D.

Director, Interchange Office, Department of Health, Mexico City, Mexico

ON November 20, 1929, nineteen years after the initiation of the Mexican Revolution, President Emilio Portes-Gil dedicated the splendid new health department building erected in Mexico City as a symbol of the spirit of social betterment dominating the activities of our generation.

From the intense sufferings and hardships of the prolonged period of political agitation, new thoughts and inspirations have arisen, suggestive of redemption and even rebirth of a nation which has wonderful possibilities for the future.

Mexico represents the fusion of two civilizations and of two races. Following economic and social laws, the more advanced European civilization would either destroy the other or submit it to a domination which would practically amount to slavery. The Christian ideals and practices of the missionaries did much to smooth the practices of the "economic man" but notwithstanding, the great majority of the Indian population remained as a very low wage earning group, unable to raise its standards of life and to enjoy the benefits of a civilization which only tended to make it more miserable and hopeless.

The problem of public health in Mexico could not be solved as an independent problem. It had to be worked into a vast scheme of development mostly economic and educational. It was for this reason that the Mexican Constitution of 1917 converted the old Board of Health of Mexico City into a Federal Department with enlarged powers, placing under its jurisdiction all matters relating to transmissible diseases, aiming to end the incompetency and failure characteristic of local management.

The enlargement of powers was slowly effected as the economic resources of the Federal Government developed. It was not until the years 1926-1927 that Federal Offices of Health were opened in all the States of the Union.

F. P. Miranda, M.D.

At this time a plan was evolved for the construction of a suitable building large enough to provide convenient quarters for the administrative and technical staff of the department.

Architect Carlos Obregón Santacilia was chosen by Dr. Bernardo J. Gastélum, who was at that time in charge of the Department, and work was begun immediately.

The architect had in mind an imposing building, worthy of the paramount importance that the affairs of public health have in this age, and from the artistic standpoint he sought to har-

Views of Headquarters of the Department of Health, Mexico City, Mexico

monize the severe and simple lines of the architecture of today with the models left to us from the old Aztec art.

As he himself said:

Ulises Valdez, M.D.

Secretary General, Department of Health

The arrangement of the building is that emanating from the needs and functions of each of the branches that form the Department of Health, and as to style, I made the only thing that could be made (we are in Mexico and in 1929), using the marvelous materials given by our soil, arranging the departments of the building as our climatological conditions demand, and combining the materials used with the natural simplicity of a functional organism . . . with architectural forms, which result from a constant purification, far from the influence of the old styles that have no reason to exist in our times and our surroundings and which could not agree with the needs of today; in this way, without the bounds of prejudice, I conceived a building in which the light and the air would be its chief ornaments and in which the arrangement of the departments would ease its functions. I have tried to evolve a Mexican style of our day, thinking as if our marvelous ancient civilization would not have been retained and as if our traditions would have continued uninterrupted until our day.

It may be well to explain to those un-

familiar with the climate of Mexico City the great importance of this basis in our architecture.

Mexico City is situated at an altitude of 7,350 feet above sea level. The air is correspondingly light, having a pressure of 585 mm. and a low conductive capacity for heat. This means that we depend more on the sun for our heating, and need a larger space for air. These facts together with the softness of our soil, that precludes the erection of any skyscrapers, are the reason for our preference for low-ample buildings provided with large courts or "patios" which admit air and sun as a basis for health. Fortunately our sun rarely hides itself beneath clouds or fogs, and thus we enjoy an exceptional, even climate all the year round without extremes of temperature.

The building may be divided into six masses composed of three floors each, two of which are central and four are lateral and all of them surrounding the "patio" in which the waters of a large fountain serve as a reflecting glass for the beauty of the structures.

The main central mass contains the head offices, and the back central lodge the central laboratories for analysis of foods and drugs.

The lateral masses are occupied by the departments which we call "Services," namely: Transmissible Diseases, Engineering, Foods, Drugs and Chemistry, Public Health Education, and Vital Statistics.

In addition, place was provided for our printing plant and library. A notable feature of the building is the mural decoration in the main council room. These representations of massive figures suggesting the ideal of hygiene were done by Sr. Diego Rivera.

Above the imposing stairways two stone sculptures, one of Dr. Eduardo Liceaga, a pioneer in hygiene, and a past president of the American Public

Health Association, the other of Dr. Gaviño Iglesias, a pioneer in bacteriology, remind us of our past struggles and give us an inspiration for the future.

We sincerely hope that the visit of our American colleagues to this building may serve as a still further inspiration for our work and aims.

REAL WESTERN ENTERTAINMENT AT FORT WORTH CONVENTION

DR. TRUMAN TERRELL

Chairman, Entertainment Committee, Fort Worth, Texas

A GLIMPSE of the West of the olden days, the West that is so rapidly passing, will be offered to visitors to the American Public Health convention at Fort Worth. The features of this entertainment will be a real western rodeo, such as can be produced only in the ranch country, and an old-fashioned southern barbecue. Fort Worth, "where Golden West and Sunny Southland meet," is enabled to offer both.

The rodeo will be staged in the great coliseum on the grounds of the Southwestern Exposition and Fat Stock Show, where Fort Worth's big livestock show and rodeo are held each March. The barbecue will be served in one of the exposition buildings preceding the rodeo on the evening of Tuesday, October 28.

Buck Lucas, former world's champion all-round cowboy, will direct the rodeo. The performers will include a number of the best known rodeo stars in the world, among whom are Leonard Ward, Rube Roberts, Mike Hastings, Oklahoma Curly, Leonard Stroud, Warren Farmer, Indian Joe, Jim Massey, Buck Stewart and others. Women performers will include such stars as Fox Hastings, Tad Lucas, Ruth Roach and several others.

On the program there will be included exhibitions of bulldogging or steer wrestling, bronc and steer riding, fancy and trick riding, wild horse race, calf roping and fancy and trick roping.

To anyone not familiar with the performances offered by the great rodeo stars, the thrill of a lifetime is promised and even those who have seen the metropolitan versions of the rodeo will find a new thrill in the Fort Worth show.

Rodeo judges will include Captain Tom Hickman, famous captain of the Texas Rangers and one of the most noted peace officers in the country; Sheriff J. R. "Red" Wright, of Tarrant County; Chief Henry Lee, of the Fort Worth Police Department; and Guy L. Waggoner, eldest son of America's wealthiest cattleman.

Music will be furnished by the Texas Christian University Band of 60 pieces, and between the rodeo numbers special entertainment features will be provided, including an exhibition by "Red" Sublett and his trick mule. Transportation from hotels to the exposition grounds will be furnished free to all visitors.

The entertainment committee wishes to make it clear that this rodeo will be no "jump-up" performance, but will be a show in which a number of the world's greatest riders, ropers and steer wrestlers will appear. All of the performers are regular participants at the annual Exposition Rodeo in Fort Worth and it is their amazing skill and daring which attract tens of thousands of visitors to Fort Worth's great show each year, and bring them back, year after year.

AIR TRAVEL AND PUBLIC HEALTH

FREDERICK L. HOFFMAN, LL. D., F. A. P. H. A.

*Consulting Statistician, The Prudential Insurance Company of America,
Newark, N. J.*

THE forthcoming meeting of the American Public Health Association at Fort Worth suggests to many of those participating the use of the airplane not only as a time saving convenience but as a means of study as to the relation of air travel to public health. In the light of thirty thousand miles of air travel I can personally bear witness to the beneficial results of air journeys not only in this country, but in Mexico, the West Indies, Canada, and Continental Europe.

The modern airplane, however, has introduced certain health hazards which cannot be treated lightly. Not only is it conceivable that infected persons are transported by means of airplanes, but transmissible diseases may otherwise be conveyed through infected insects, plants, etc. The sanitary supervision of air travel and the possibility of quarantine of air passengers and goods as yet has hardly received consideration, but the subject is one well worth studying.

In Europe air ambulances for the conveyance of sick persons have attracted considerable attention and were dealt with at the International Convention. The conveyance of doctors to isolated localities to give prompt treatment, as well as the transportation of medicine, particularly antitoxins, has been made a matter of record in a number of instances, but to me the main aspect of air travel is the beneficial results to passengers who derive great advantages from even a few hours of journeys in the upper air. Personally I have never met with any disadvantages, and the so-

called risk of air sickness is largely exaggerated.

The questionnaires sent out to nearly a thousand registered pilots asking information as to the benefits of flying on health are almost uniformly in the affirmative. In not a single instance have the reports been to the effect that flying has been detrimental, regardless of the extraordinary strain on the nervous system on the part of pilots. Thus out of 895 replies returned, 713 were emphatically in the affirmative, while the remainder were neutral or ill defined. Out of the 895 only 40 reported having had air sickness, and these were mostly in connection with stunting performances.

It has been suggested that some of the members expecting to participate in the Fort Worth meeting may make use of the airplane for both rapid transportation and observational purposes. Dallas and Fort Worth are important air centers which can be easily reached by a number of lines. From Birmingham, Ala., the Delta Air Service makes the trip to Fort Worth in 2 days of about 4 hours flying each day at a cost of \$46.00. This is a wonderful trip full of interesting views.*

A short journey can be made from Tulsa, Okla., to Fort Worth, Tex., in about 4 hours at a cost of \$17.00. But the main attraction is the opportunity of air trips to Mexico. These can be easily made from Fort Worth and Dallas

* For a more detailed article, see Stone and Webster, *Journal*, April, 1930, pp. 462-481.

over the Southern Air Transport Line, leaving Fort Worth at 8.55 in the morning, arriving at Brownsville at 3.45 in the afternoon, leaving Brownsville next day at 8.15 in the morning and arriving at Mexico City at 1.45 p.m. The air rate from Fort Worth to Brownsville is \$28.44, while the rate from Brownsville to Mexico City is \$87.50. These rates, of course, are higher than rail rates but the time saving is considerable. Thus the train leaves Mexico City at 8.50 p.m. and reaches Laredo, Tex., 34 hours later, while the air time is only 5½ hours including stopping time at Tampico.

No greater opportunity is likely to present itself for many years to members of the American Public Health Association to become familiar with the new spirit of Mexico in health and medical matters. Progress in Mexico during the last five or six years in this respect has been prodigious. It was but recently my privilege to attend the Latin-American Congress in Mexico City in connection with which I made the entire trip from Birmingham, Ala., to Mexico City by air without the slightest inconvenience or delay. For sight-seeing purposes it is difficult to match this wonderful journey which includes considerable flying over the waters of the Gulf and the lagoons of

Southern Texas. The trip, of course, can easily be extended to other parts of Mexico, particularly Vera Cruz and Yucatan on the one hand, and Guatemala on the other. The rates, considering the enormous amount of saving in time, are not excessive or prohibitive.

Modern Mexico will astonish Americans who have never visited it. The developments in public health service during recent years have largely followed American lines of procedure. The new building of the Public Health Service of Mexico has nothing in America to outmatch it. The health officials are men of high standing in their profession, while everywhere one may meet physicians and surgeons of outstanding qualifications. There are some very admirable clinics in Mexico City worthy of a visit, while the historical attractions of the city and other parts of Mexico offer no end of opportunities, arousing the imagination and giving delight to the mind of searchers of the picturesque. I therefore hope that many of the visiting members of the American Public Health Association will be able to take advantage of the extension trip. I can conceive of no greater attraction to induce members to participate in the Fort Worth meeting than this additional pleasure of a possible visit to Mexico City.

Fort Worth Municipal Airport

ASSOCIATION NEWS

ORGANIZATION OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

THE Constitution of the Association as amended by the Association at its Fifty-Eighth Annual Meeting and the new By-laws adopted by the Governing Council at that meeting included a number of changes calculated to simplify the organization of the society and to provide a scheme to permit better coördination of its many activities. The principal changes were:

1. Creation of the office of President-elect and the inclusion of this officer on the Executive Board in place of the retiring President

2. The creation of the new office of Chairman of the Executive Board

3. The election of 2 members of the Executive Board each year for a 3-year term in place of electing 3 new members each year for a 2-year term

4. The creation of 4 standing committees appointed by and responsible to the Executive Board, with a view to placing all of the Association's activities under the direction of these committees. It was expected also that these committees would afford a channel for coördinating the work of section committees with each other and with the work of the Association. The composition and functions of these committees are described on pages 866 and 867 of the August issue of the JOURNAL.

The new By-laws did not take away the authority of the Executive Board to appoint special committees from time to time, and under this authority the Board has appointed the following special committees:

Sedgwick Memorial Medal Committee
Committee on Federal Health Legislation
Committee to Extend the Association's Influence in South and Central Americas
Committee to Coöperate with the Director of the Census
Central Finance Committee
Executive Committee of Executive Board

The sections and section committees retain their previous independence under the new plan. However, to provide an opportunity for correlating the work

of the sections with that of the Association, the section committees have been asked to report to one of the standing committees as well as to their respective sections.

Except for the fact that no appointment has been made to the office of secretary of the Committee on Research and Standards, the new organization has been completed as indicated by the diagram herewith presented.

The personnel of the Governing Council is shown on page XX of this issue of the JOURNAL. The personnel of the Executive Board and the standing committees follows:

Executive Board

W. S. Rankin, M.D. (1931), *Chairman*

ANNUAL MEETING INFORMATION

REDUCED RAILROAD FARES

REDUCED railroad fares on the Identification Certificate Plan have been authorized by the several Passenger Associations in the United States and Canada, which will entitle all members and dependent members of their families to a special rate of a fare and one-half for the round trip to Fort Worth.

Under this plan an Identification Certificate *must be presented* to the ticket agent when purchasing tickets. (One has been mailed to every member of the Association.) This is the ticket agent's authority to issue to delegates and dependent members of their families a round-trip ticket to Fort Worth at the reduced rate. The routing should be specified when making the purchase, for the routing covered by the round-trip ticket cannot be changed at Fort Worth.

All return tickets must be validated, before leaving Fort Worth, by the ticket agent who will be on hand at the Registration Desk in the Hotel Texas, or by the regular ticket office.

It is suggested that all members consult their local ticket agents in regard to dates of sale and return limit of reduced-

rate tickets, as these limits vary according to distance from Fort Worth.

The Passenger Associations have authorized a special rate of fare and three-fifths for delegates who are taking the post-convention tour to Mexico City. They should purchase tickets with return limit 30 days from date of sale.

Either fare and one-half or fare and three-fifths should be specified when purchasing tickets, depending upon whether or not the delegate returns immediately from Fort Worth or goes on to Mexico City.

SPECIAL TRAINS TO FORT WORTH

ARRANGEMENTS have been made for delegates to Fort Worth to travel together in special trains or through cars from various points in the United States. St. Louis, Memphis, New Orleans, Portland, and Los Angeles have been selected as concentration points. A communication has been sent to the membership setting forth the advantages of such travel, and maps showing special train movements and schedules for special cars are repeated here for the sake of convenience. (See pages 1134, 1135 and 1136.)

SCHEDULE FOR SPECIAL TRAINS TO THE ANNUAL MEETING

OCTOBER 27-30, 1930

AMERICAN PUBLIC HEALTH ASSOCIATION, 370 Seventh Avenue, New York, N. Y.

AMENDMENT TO THE CONSTITUTION

IN accordance with the provision in the Constitution regarding amendments, the following amendment, which is to be offered at the forthcoming Annual Meeting, is hereby published as prescribed.

RESOLVED that Article III, Section A, of the Constitution, shall be amended by the addition of the following at the end of this section:

6. A representative to be designated by each regional branch. Such representative shall be a Fellow of the American Public Health Association.

This amendment, if approved by the Governing Council, will be presented to the Fellows present at the Fort Worth meeting. It requires a two-thirds vote of the Fellows present and voting, for ratification.

NEW MEMBERS

Health Officers Section

- Otis L. Chason, M.D., Opelika, Ala., County Health Officer, Lee County
 Gustav J. Hildebrand, M.D., Sheboygan, Wis., Health Officer
 W. S. Hull, M.D., St. Joseph, Mo., County Health Officer
 Thomas H. Johnston, M.D., Athens, Ga., Commissioner of Health
 Dr. Walter Kleberg, Galveston, Tex., City Health Officer
 W. F. Lunsford, M.D., Poteau, Okla., Director, LeFlore County Coöperative Health Unit
 Alexander C. McKean, M.D., Provo, Utah, Director, Utah County Health Unit
 W. M. Newman, M.D., Spokane, Wash., County Health Officer
 Zenas V. D. Orton, M.D., Salem, N. Y., Health Officer
 J. W. Pittman, M.D., Belton, Tex., County Health Officer
 William Plattner, Brattleboro, Vt., Health Officer
 Josiah B. Redfield, M.D., North Platte, Nebr., City Physician
 Luther F. Rhodes, M.D., Fort Worth, Tex., County Physician
 Dr. Hugo Robinson, Albany, Ga., Commissioner of Health
 William V. Sanford, M.D., Murfreesboro, Tenn., Assistant Director, Rutherford County Health Department
 George H. Spivey, M.D., Wink, Tex., Director, Winkler County Health Unit

Laboratory Section

- Helene T. Bennett, A.M., Yuma, Ariz., Director of Clinical Laboratory, Thomas Laboratories
 E. H. Bramhall, B.S., Salt Lake City, Utah, Director, State Board of Health Laboratory

- Clarence R. DeYoung, B.S., Chicago, Ill., Senior Bacteriologist, Department of Health
 Hugh N. Heffernan, B.S., New Orleans, La., Field Bacteriologist, State Board of Health
 Archie H. Robertson, Ph.D., Albany, N. Y., Director, Food Laboratory, State Department of Agriculture and Markets
 Richard F. Zedlitz, D.V.M., Ballinger, Tex., City Milk Inspector

Public Health Engineering Section

- Aaron D. Chandler, Fort Worth, Tex., Chief Plumbing Inspector, Engineering Department
 O. K. Hobbs, Abilene, Tex., City Engineer
 Leonard H. Male, Salt Lake City, Utah, State Sanitary Engineer
 M. S. Kumaraswamy Pillay, Trivandrum, India, Section Officer, Water Works (Assoc.)
 John R. Hoy, Jacksonville, Fla., Sanitary Engineer, Wallace & Tiernan Co.
 G. T. Russell, Lufkin, Tex., Superintendent, City Water Works

Food, Drugs and Nutrition Section

- Leo F. Barthelme, B.V.S., Parsons, Kans., Milk and Dairy Inspector

Child Hygiene Section

- James J. Waring, M.D., Denver, Colo. (Assoc.)

Public Health Education Section

- John H. Bursleson, San Antonio, Tex., recently Chairman, Board of Health
 William J. Johnson, M.D., San Antonio, Tex., Superintendent, State Hospital
 Vera H. Jones, M.D., Denver, Colo., School Physician

DECEASED MEMBERS

Kenneth Allen, New York, N. Y., Elected Member 1915, Fellow 1922

Charles O'H. Laughinghouse, M.D., Raleigh, N. C., Elected Member 1920

George Collins, Raleigh, N. C., Elected Member 1928

Charles P. Fox, M.Sc., Miamisburg, O., Elected Member 1919

George C. Gensheimer, Erie, Pa., Elected Member 1919

Carson V. Merritt, M.D., Flint, Mich., Elected Member 1923

Fowler A. Watters, M.D., Lockport, N. Y., Elected Member 1927

APPLICANTS FOR FELLOWSHIP

HEALTH OFFICERS: Benjamin Goldberg, M.D., Chicago, Ill.; Eugene H. Sullivan, Nutley, N. J.; F. Edward Whitehead, Morristown, N. J.

FOOD, DRUGS AND NUTRITION: Joseph Parke Bushong, M.D., Los Angeles, Calif.

CHILD HYGIENE: Pauline B. Williamson, New York, N. Y.

INDUSTRIAL HYGIENE: Daniel L. Lynch, M.D., Boston, Mass.

PUBLIC HEALTH ENGINEERING: Ralph E. Tarbett, Washington, D. C.

CORRECTIONS

Edward Desmond Hopkins, Fort Worth, Tex., listed in the September JOURNAL as Unaffiliated, has since applied for fellowship in the Public Health

Engineering Section of the Association. The name of Charles Frederick Adams was published in the September JOURNAL as Charles Henry Adams.

MEMBERSHIP LIST

Publication of the List of Members of the A. P. H. A. has been delayed. Announcement of date of publication will be made in November JOURNAL.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Decrease of Hookworm—Hookworm infection is still widespread geographically in the southern states. The Pythagoristic standardization of carriers versus patients predicated on hookworm oölogy and used as a basis in the very interesting studies conducted in Alabama should be restudied and checked, both from the standpoint of objective and subjective, measurable and unmeasurable factors, and until fully confirmed should not be taken as justifying health officers in assuming a position that light cases of hookworm infection are to be ignored clinically or to be discouraged from or prejudiced against treatment. County health officers should establish their hookworm eradication programs through the agency of the family physician who should give the treatments. Education should function through schools, churches, industries, and public health nurses.—C. W. Stiles, *Decrease of Hookworm Disease in the United States*, *Pub. Health Rep.*, 45, 1763 (Aug. 1), 1930.

Influenza in Cleveland—There were reported 5,922 cases of influenza in Cleveland during the 2 months, December and January, 1928-1929, and 315 deaths due to this cause. It is estimated that 17,300 cases of influenza occurred. As compared with the winter months of the 5 preceding years, the winter of 1928-1929 had an excess of 42 per cent in total deaths. Beyond the age of 5 years the fatality rate increased with age. The highest case rates occurred in the congested parts of the city. The peak of incidence in 16 of the 18 districts into which the city was divided occurred in the week of December 23.

In the other two districts the peak occurred in the preceding week. Secondary peaks occurred in five districts, all in the southeastern part of the city. All the secondary peaks occurred in the week of January 6.—H. W. Green and H. L. Rockwood, *The 1928-1929 Influenza Epidemic in Cleveland*, *J. Prev. Med.*, 4, 251 (July), 1930.

Diphtheria Prevention in Philadelphia—In June, 1930, the third annual campaign for immunization against diphtheria was conducted. It is estimated that 70 per cent of the public school population and 60 per cent of the parochial school children have been protected with a resulting decrease of 50 per cent in the incidence of this disease. There were established in June 98 points where toxin-antitoxin was administered free to 23,000 children. Publicity was given through circulars and campaign literature, news articles and advertisements in the daily papers, radio announcements, posters in street cars, buses and taxicabs and notices on billboards in various parts of the city.—H. L. Hartley, *Campaign for Immunization against Diphtheria*, *Bulletin Philadelphia Health Dept.*, Aug., 1930.

Morbidity Area—The following suggestions have been made as criterions in determining the admissibility to the proposed morbidity reporting area of states having 500,000 or more population:

1. The state shall be in the registration areas for births and deaths.
2. The state shall have a morbidity reporting law or regulations requiring—A. An immediate report to the local health officer of each case of diphtheria, infantile paralysis, measles,

smallpox, scarlet fever, typhoid fever, tuberculosis, whooping cough, giving name, age, sex, and address. B. (1) A daily report by the local health officer to the State Health Department of each case reported to him, giving the above details of name, age, sex and address. (2) A report at least once weekly of the total cases of each disease reported during the preceding week, and a monthly summary of each disease by age and sex.

3. A check made each month on the deaths

from the above mentioned diseases to ascertain whether or not they have previously been reported as cases.

4. The state shall attain a suitable fatality rate for diphtheria, measles, scarlet fever, typhoid fever, and whooping cough.—

R. C. Williams, The Proposed Morbidity Reporting Area, *Pub. Health Rep.*, 45, 1781 (Aug. 1), 1930.

LABORATORY

C. C. YOUNG, D. P. H.

A SIMPLE METHOD FOR INDICATING THE VARIOUS SUGARS USED IN THE CARBOHYDRATE SERIES

R. V. STONE, D. V. M.

*Director, Bureau of Laboratories, Los Angeles County Health Department,
Los Angeles, Calif.*

IN the past, laboratories have resorted to various methods of marking test tubes containing various carbohydrates for identification of organisms through their fermentative reactions. Two methods commonly in practice consisted of actually labelling the test tubes with frosted numbers indicating the sugars, or of coloring the cotton stoppers with aniline dyes, using a different color for each carbohydrate. Both methods were objectionable since either the test tubes had to be carefully sorted for the sugar they were to contain, or the dye on the stoppers was frequently transferred to the worker's fingers. The method of marking each tube with a wax pencil is the most common. It has the objection of consuming considerable time, and involving considerable processing in cleaning the tubes.

The Bureau of Laboratories of the Los Angeles County Health Department has for some time had in use a simple scheme developed by the writer. Glass beads commercially designated as "No.

2, cut beads" can be obtained in a variety of colors. The most practical series of colors are: red, opal, amber, light blue, black and dark green. A color is assigned to each sugar and used throughout the laboratories. Red beads indicate dextrose; amber mannite; opal maltose; blue lactose; black saccharose; and dark green plain broth.

It is a simple matter, in use, to recognize the sugar by the color of the bead. The identification charts which give the reactions of various organisms with sugars are marked at the top in colors similar to those of the beads. The sugar series is taken from the rack after incubation and the beads quickly matched with the same colors on the chart. Recording of reactions is rapidly made.

When washing the tubes after the tests the broth is emptied through a sieve and the beads collected are rapidly sorted according to their colors and are ready for use in the next batch of medium.

A STORAGE BIN FOR LABORATORY GLASSWARE

C. S. MUDGE, F. A. P. H. A.

*Associate Bacteriologist, Division of Dairy Industry, University of California
College of Agriculture, Davis, Calif.*

DUE to the reorganization of the service room in the bacteriological laboratory of this institution, overcrowding was imminent, which was solved by the installation of storage bins described below.

The measurements were based on the size of petri dishes, but other glassware has been found to fit nicely into the space. A series of upright partitions was erected, upon the outside edge of which were fastened strips of lumber— $1\frac{3}{4}'' \times 1\frac{3}{4}''$ —ruled out as shown in Figure I. Gates or slides were made to fit into these grooves.

Petri dishes were placed on the floor of the bin—three each way—and other dishes were piled upon these, a slide being inserted as the pile grew. Thus, it was possible to receive and dispense petri dishes, always having them easily accessible. Although in one of the bins the dishes are 80 high, no breakage has been noticed due to the weight of the superimposed glassware.

Figure I

For dilution bottles we have found these bins convenient. In this case each layer has been separated from the one above by egg case flats.

One and two liter flasks have been stowed successfully by inverting some of the flasks between the upright ones.

Although the height of these bins may be varied, those in this laboratory are 7' high, which has proved entirely satisfactory.

In teaching laboratories, where at times large numbers of dishes and flasks are issued for exercises, it has been found that the flexibility of this method of storage is a great help.

Figure II is given to show the plan of the bin.

Figure II

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Appendicitis Mortality—In the 19 years since 1911 a steady upward trend in appendicitis mortality rates has been observed among Metropolitan policy holders. The year 1929 had one of the highest appendicitis death rates on record. Comparing the first 5 with the last 5 years of this 19-year period, we find an increase of 20 per cent in the death rate for white males and of 14 per cent for white females.

The increases in fatalities have varied by age. For children under 5 years, the appendicitis death rate in 1925-1929 was 11.5 per 100,000 for white males, an increase of 126 per cent since 1911-1915. For white females, the recent death rate at this age period was 9.2 per 100,000, an increase of 92 per cent since 1911-1915. Only between 10 and 19 years of age was there any decrease in appendicitis mortality for both males and females. Here the decrease was about 3 per cent for white males and between 10 and 15 per cent for white females. Beginning with adult life, however, the appendicitis death rate showed marked increases in the period 1925-1929, as compared with 1911-1915. During adult life it was generally true that the higher the age the greater the rise in mortality.

In general, appendicitis mortality among males is higher than that of females. In 1911-1915, the death rate of males exceeded that of females by 26 per cent. In 1925-1929, in view of the greater increases in mortality among males than among females, the excess in the death rate of males had risen to 33 per cent. As measured by these data, the disease seems not to be equally common in males and females, as has been

suggested in standard texts on the subject.

Much of the recorded increase in appendicitis mortality in recent years seems to be real and is not due in large part to greater precision in reporting. Beginning with 1911 great care has been exercised in securing more complete statements of the causes of death from physicians and surgeons. It is believed that the statistics included in this survey are as nearly complete as such data ever will be. Hence, the recorded increase in appendicitis mortality among these policy holders must reflect, by and large, a real change in the factors leading to fatal appendicitis. At the present time we do not know what those factors are.

In former years, it was assumed that high appendicitis rates prevailed in years characterized by high prevalence of general intestinal infections. The sharp fall of death rates for diarrhea and enteritis since 1911, resulting from the protection of milk, and other food supplies, suggests, however, that food infections of the kind prevailing years ago were not a primary factor in bringing on the recent increase in appendicitis mortality.

The subject is of sufficient importance to warrant well founded and critical inquiry into the prevailing and indisputably increasing incidence of fatal appendicitis. More than 18,000 deaths from the disease occurred in the United States during 1928.—*Stat. Bull., Met. Life Ins. Co.*, 1: 1-3 (July), 1930.

Mortality Statistics. 1929—

Maine—The Department of Commerce announces that there were 11,353 deaths in Maine during 1929 as com-

pared with 11,005 in 1928. The number of deaths (523) from influenza in 1929 was almost double the number (278) which occurred in 1928, and this increase was mainly responsible for the increase in the total number of deaths which occurred during the year 1929, as compared with 1928. The number of deaths (2,189) due to diseases of the heart represents the largest number for the 4-year period. Cancer, with 1,120 deaths, also showed a continuous increase. The increase in the number of deaths from diarrhea and enteritis in children under 2 years of age was especially noticeable in the 2 years, 1928 and 1929.

Most significant among the decreases in deaths were those due to nephritis (877 to 825), and cerebral hemorrhage and softening (1,134 to 1,090). Decreases were also reported for a number of the epidemic and infectious diseases, including diphtheria, scarlet fever, typhoid fever, whooping cough and others. None of these, however, was responsible for an appreciable number of deaths in the state.

The number of deaths from accidental and unspecified external causes decreased from 638 in 1928 to 585 in 1929. Especially noteworthy was the decrease in the number of drownings from 114 to 81. This decrease, however, was more than offset by the large increase from 115 to 151 in the number of deaths due to automobile accidents and an increase of 20 in the number of suicides.

Montana—There were 5,742 deaths in Montana during 1929 as compared with 5,780 in 1928.

The numbers of deaths from influenza in 1928 and 1929 greatly exceeded the number from this disease in 1927 and were in a considerable measure responsible for the increase in the total number of deaths in this state for the latter years. There was an increase each succeeding year reported from cancer and

other malignant tumors, diseases of the heart, appendicitis and typhlitis, and a few other less important causes of death.

Other increases were from measles, 8 to 50, typhoid and paratyphoid fever, from 16 to 31, and puerperal septicemia, from 28 to 42. The number of deaths from tuberculosis was less than for any previous year shown in the table, and noteworthy decreases were reported in the number of deaths from cerebral hemorrhage and softening and diabetes mellitus.

The number of deaths due to accidental and unspecified external causes was practically the same as in prior years, but for the years 1928 and 1929 there was a considerable increase in the number of deaths due to automobile accidents, as compared with the years 1926 and 1927.

Nevada—Nevada reports 1,199 deaths in 1929—the first year of its admission to the registration area.

The principal causes of death in order of their importance were diseases of the heart, 165; pneumonia, all forms, 98; tuberculosis, all forms, 87; cancer, 80; and nephritis, 72.

Of the deaths due to accidental and unspecified external causes, the greatest number was caused by automobile accidents, with 45, mine accidents second, with 15, and railroad accidents and accidental falls having the same number of 14 each.

North Dakota—There were 5,421 deaths in North Dakota during 1929 as compared with 5,513 in 1928.

The same 5 causes of death ranked the highest during the 4 years 1926 to 1929; in 1929 they were in the following order: diseases of the heart (796), congenital malformations and diseases of early infancy (486), cancer (457), pneumonia, all forms (424), and cerebral hemorrhage and softening (420). Other causes which were among the next highest during this period were nephritis, influenza, and tuberculosis, all

forms. The deaths from diseases of the heart, pneumonia, all forms, and influenza in 1928 and 1929, greatly exceeded those in 1927, while the deaths from tuberculosis were noticeably fewer.

In 1929 marked increases from 1928 were reported in deaths from measles, meningococcus meningitis, diphtheria, whooping cough, and diarrhea and enteritis, under 2 years; decreases in deaths were shown for diabetes mellitus, scarlet fever, and acute anterior poliomyelitis.

The greatest number of deaths in 1929 from accidental and unspecified external causes was due to automobile accidents (88 as compared with 79 in 1928), followed by accidental falls and accidental drowning.

Wisconsin—The Department of Commerce announces that there were 31,287 deaths in Wisconsin during 1929 as compared with 31,788 in 1928.

Deaths from measles increased from 12 in 1928 to 86 in 1929, and from whooping cough from 79 to 121, but even these large numbers in 1929 compare favorably with the very much larger ones in 1926 (154 and 175, respectively).

The deaths from diseases of the heart and cerebral hemorrhage and softening increased steadily and considerably in each year from 1926 to 1929, but, on the other hand, deaths from diphtheria, tuberculosis, all forms, diarrhea and enteritis, under 2 years, and congenital malformations and diseases of early infancy decreased, similarly, throughout this period.

In addition to those mentioned, other important decreases in deaths from 1928 to 1929 were from influenza, diabetes mellitus, pneumonia, all forms, and nephritis.

Deaths from suicide increased from 404 in 1928 to 453 in 1929.

The deaths from accidental and unspecified external causes increased continuously from 1,790 in 1926 to 2,268 in

1929, and the increase of 118 from 1928 to 1929 was nearly accounted for by the increase in deaths from accidental falls (420 to 518). While the deaths from automobile accidents, excluding collisions with railroad trains and street cars, decreased by 8 from 1928 to 1929, the number of deaths from this cause increased from 384 in 1926 to 612 in 1929, or approximately 60 per cent in the 4-year period.

Delaware—There were 3,132 deaths in Delaware during 1929 as compared with 3,196 in 1928.

The decreases in deaths from diseases of the heart, nephritis, typhoid and paratyphoid fever, and syphilis in 1929 as compared with 1928 were almost balanced by increases from pneumonia, all forms, influenza, whooping cough, and diabetes mellitus.

There was a steady decline in the number of deaths from syphilis, tuberculosis, all forms, and nephritis from 1926 to 1929.

There was a considerable decrease in the number of deaths from accidental and unspecified external causes in 1929 as compared with 1928, the decrease being more than accounted for by decreases in accidental drowning, accidental falls, and automobile accidents, the last of these causes dropping from 75 to 57.—*Mortality Statistics: Provisional Summaries*, U. S. Census Bureau.

Public Health Conditions and Administration in Burma—Burma is divided into 7 civil divisions for purposes of administration. The civil surgeon of each district is also the medical officer of health and is required to advise all local authorities in his district on matters of public hygiene. The local authorities employ public health workers. In 1927, they engaged 84 public health inspectors, 27 of them in rural areas. Birth and death registers are in charge of village headmen and are inspected by district health officers. Registration is

inaccurate and incomplete because of illiteracy and the fact that registrars have to bear the expense of submitting returns. The provincial birth rate was recorded as 25.08 per 1,000 in 1927; the rural birth rate was 24.70 and the urban 27.98. The provincial death rate was 19.55 per 1,000, the proportion of males per 100 females being 114; the rural rate was 17.38, the urban 36.21. Infant mortality was recorded as 198 per 1,000, 118 male infants dying to every 100 females, 51 per cent of these deaths being between the ages of 2 and 6 months.

There were 4,528 deaths from cholera, 1,704 from smallpox and 3,508 from plague. Urban areas were affected more by these diseases than rural, especially in the case of plague. Cholera is combated by inoculations and vigorous campaigns are carried out whenever cholera breaks out in epidemic form. Vaccination for smallpox is carried out by public vaccinators employed by local authorities. From cases treated in hospitals, statistics show case mortality to be 7 per cent among vaccinated and as high as 32 per cent among unvaccinated persons. Plague is combated by rat destruction and inoculation. There were 102,859 persons inoculated in 1927, of which 60,235 were done in towns. Venereal disease is known to be very prevalent but there are no reliable statistics available. Syphilis was found to be present in 10 per cent of 897 post-mortems in one of the large hospitals.

Local authorities are responsible for expenditures of water supply, drainage, road cleaning and watering, sewage disposal, public markets and abattoirs. They receive an annual government contribution to maintain these public health works. Municipal committees seldom receive any grant. Government inspection of schools and school children is compulsory in government high and middle schools.—Major H. C. C.

Cherry, *J. Roy. San. Inst.*, 51: 20–28 (July), 1930.

Mortality Experience of the First Six Months of 1930—A new record for low mortality has been registered for the winter and spring seasons of 1930. This applies to Canada as well as to the United States. In the latter, the white population has enjoyed better health than during the corresponding period of any previous year; and the death rate of the colored people has never been so low—with a single exception. The improvement has probably extended to all ages of the population—although this cannot be stated unreservedly at this writing. It is certain, nevertheless, that the chief scourges of childhood are taking a smaller death toll than ever before; that tuberculosis, which causes death chiefly in early adult and middle life, is recording a death rate far below the previous minimum; and that the mortality rates from several diseases, which are important factors in later life, have shown noteworthy declines in 1930.

These statements are based on the mortality experience of approximately 19,000,000 persons—the industrial policy holders of the Metropolitan Life Insurance Company in the United States and Canada. The health records of this large cross-section of the population have invariably proved, in the past, to be accurate indices of the health conditions prevailing in the general populations of both countries.

As in 1929, a large reduction in the tuberculosis death rate to a new minimum bids fair to be the outstanding public health fact of the year. The figure for the first half of 1930 was 85.6 deaths per 100,000 policy holders. Both white and colored policy holders have shared in the decline, with the former showing the greater drop in death rate.

The improvement in the diphtheria mortality rate is an outstanding item in

the health record of 1930, to date, and is second in importance to the splendid record for tuberculosis. The diphtheria death rate has dropped approximately 27 per cent in a single year. Unless unexpected epidemic prevalence of this disease is encountered at some time during the latter half of the year, 1930 will not only register a new minimum death rate for diphtheria, but will mark the largest year-to-year drop ever recorded. Still another favorable item in the 1930 health report is the record for diseases related to childbearing, which have every prospect of recording a new minimum death rate this year.

The absence of any widespread prevalence of influenza has resulted in about the normal winter and spring death rate for that disease. The drop in influenza mortality has been reflected in a considerable decline for pneumonia. The decreases recorded this year for heart disease and chronic nephritis are also

due, in part, to the lower prevalence of influenza which, when epidemic, always hastens the deaths of many persons who suffer from chronic diseases. A slight decline in the cancer death rate has persisted throughout the half-year. The diabetes death rate (19.6 per 100,000) may be compared with 21.0 for the like period of 1929.

Suicides have been a little more frequent than in the corresponding part of 1929, while the homicide death rate and that for fatal accidents have dropped slightly. The mortality from automobile accidents is higher than ever before at this time of the year. Thirty-eight hundred and ninety-nine Metropolitan Industrial policy holders were killed in 1929 in motor vehicle accidents; and the estimated loss of life in the United States from this cause was 31,400. These totals will probably be exceeded this year.—*Stat. Bull., Met. Life Ins. Co.*, 11: 3-6 (July), 1930.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

PROGRESS REPORT OF PULASKI, VA., RESERVOIR STUDIES *

F. J. SETTE

Associate Professor of Sanitary Engineering, Virginia Polytechnic Institute, Blacksburg, Va.

THERE is usually objection on the part of laymen to stored water supplies. There are various reasons for this objection. In the first place, stored water is classed in their minds as stagnant. Again, odors and tastes are at times objectionable in impounded water, enhancing the popular dislike. Other troubles, too, add to the general distrust.

Many supplies in Virginia depend mainly on springs of unknown origin and uncertain flow. When it becomes essential to provide a more certain supply, it will be necessary to impound surface waters. Therefore, at the suggestion of Richard Messer, Chief Engineer of the Virginia State Department of Health, a study of an existing reservoir—that at Pulaski—was begun. This investigation is to answer, if possible, questions as to odors and taste, corrosion, tuberculation, and the like. The study was to include not only the physical, chemical and biological conditions, but also run-off. Unfortunately, since the supply is not entirely metered, this phase of study has not yet been started. The microscopic life has not as yet been so prominent; few organisms having developed in quantities large enough to be interesting. The report, therefore, resolves itself into a study of the physical and chemical conditions.

The present supply is obtained from a watershed lying in the foothills of Draper Mountain approximately 3 miles southwest of Pulaski. This shed has an area of 1,746 acres, or 2.73 square miles, is entirely owned by the city, and is adequately protected. The reservoir impounds about 1/5 billion gal. of water. At the point of sampling, the depth is about 50 ft. when the surface of the water is level with the spillway. The sampling point is directly opposite the intake. The reservoir is Y shaped with the intake at the end of the Y stem. At this point, it is about 215 ft. wide and 50 ft. deep when full.

The study began on March 17 of this year. Apparently the spring overturn had occurred several weeks before, and was nearly at an end. It will be noticed that for 3 weeks the water was in a state of unstable equilibrium, finally having its last overturn on March 31. After

TABLE I

Temp. ° F.

Depth	March 17	March 24	March 31	April 7
Top	47.5	43.4	44.5	47.5
10'	47.2	45.2	44.5	47.5
20'	47.1	44.6	44.5	47.5
30'	43.6	44.5	44.3	45.7
40'	43.6	44.1	44.3	45.5
Bottom	43.8	44.1	44.1	45.5

* Presented at the Second Annual Conference of the Virginia Water and Sewage Works Association at Norfolk, Va., June 19-20, 1930.

this date, the summer stagnation began in earnest. As the weeks progressed the stratification became more pronounced.

FIGURE I
Pulaski Reservoir Studies.

Table I gives the temperatures for the weeks around circulation. It can be seen that the reservoir was directly stratified on March 17, but this condition was only temporary. A cold snap, that week, overturned the water, which accounts for warmer bottom tempera-

FIGURE II
Pulaski Reservoir Studies.

tures on March 24. On March 31, the entire body of water was in circulation, although there is a difference of 0.4° F. between the top and bottom. It can be said, then, that for the period under discussion the reservoir was in circulation.

It is probable that the lake was in circulation for a month before observation began.

The averages for March, April, May, and June are plotted (see Figure I) to show the trend in stratification. It will be noticed that the zone of circulation is very clearly limited to the upper 10 ft. of the lake. This is even more apparent in Figure IV. On the other hand the zone of stagnation seems to begin at the 30-ft. depth. On June 30 the dissolved oxygen content was 1.06 p.p.m. at this level, whereas the average for the month was about 3.80. This shows that the oxygen is being used up very rapidly at this point.

Figures II and III show the trend of the dissolved oxygen and carbon dioxide content of the various layers for the different months.

What effect has stratification on the

FIGURE III

Pulaski Reservoir Studies.

quality of the water? The question can be answered by the results obtained. It will be seen on Figures II and III that during the period of overturn, the water was fairly well aerated and decarbonated, but as stratification begins, a similar condition starts in the dissolved gases. The dissolved oxygen in the zone of circulation shows how well aerated that zone is. But, as the depth increases, the oxygen becomes depleted; being used up in the oxidation of the organic matter which settles to the bot-

tom. On the other hand, the carbon dioxide increases with the depth, a natural consequence of decomposition.

Curves showing the relationship between temperature, dissolved oxygen and carbon dioxide at various depths for June 30 are plotted on Figure IV. It will be noticed that at 20 ft. there is plenty of oxygen and little carbon dioxide.

FIGURE IV

Various organisms have been found, but the most prolific thus far are pandorina, dinobrion and glenodinium. These organisms will give trouble when they become more numerous. Some

other organisms have been found which are interesting, but thus far they have not been identified. Since these organisms are among the higher forms of life, their identification has been allowed to wait.

Water at the Pulaski reservoir is drawn from about the 20-ft. level. Thus far this level has been well within the zone of circulation and transition. However, as the season advances, it may be that it will fall in the stagnant zone. Then trouble may be expected not only from organisms, but also from stagnant water. Later on, tap samples will be taken to determine which of these two is responsible for whatever troubles may develop.

It will also be noticed that the CO_2 content of the water at the 20-ft. level is now 2.6 p.p.m. and is increasing rapidly. Since the water is very soft, most of the CO_2 is aggressive and the water may become highly corrosive, causing red water. This condition will occur undoubtedly in the late summer. However, the remedy can be determined only after a complete study, the results of which I hope to present next year.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

The Mortality of Shopkeepers and Their Assistants—Tables accompanying this article show that youths predominate as shop assistants, e.g., a comparative statement of age group proportions showing that per 1,000 total females there are employed in this group at the age of 16 years, 3,048; at 20 years, 2,285; at 25 years, 1,063; at 35 years, 542; at 45 years, 339; at 55 years, 187; at 65 years, 102; and at 70 years, 41. For the same ages the total employed per 1,000 occupied and retired persons are, respectively: 1,392; 1,234; 1,061; 788; 532; 310; 200; 142. Males are relatively more numerous than total occupied males at all ages under 35 and progressively less so afterwards. This is true also for females, in whose case the reduction in old age is even more extreme.

Evidence as to the health of shop assistants is confined to that of males during 1921-1923. Those employed in (1) businesses for the sale of fish, meat, greengrocery and milk; (2) businesses for the sale of grocery and provisions, and (3) businesses for the sale of textiles and clothing, are considered (tables accompany). It is noted that the mortality of those in fish, meat, etc., shops and in drapery shops, which form almost 40 per cent of the whole number of shop assistants, is considerably above that of their employers. In fact, mortality seems to be high for youths employed as shopkeepers and it seems that the highest mortalities are among those employed in open air conditions (fish, meat, greengrocery and milk trades).

The diabetes mortality is excessive for both employers and employees and especially for those engaged in the food dis-

tribution trades. Drapers, who are not especially subjected to overeating, form the only category not returning excessive mortality from diabetes.

Phthisis for shop keepers is below the average but for shop assistants is above the average. Here again it is found that, so far as the fresh air associated with open air trades proving a protection against respiratory diseases, mortality from respiratory diseases was over the average for this group, and under the average elsewhere.

If cirrhosis of the liver be accepted as an index of alcoholism, as it appears to be much the best provided by the returns, shopkeepers as a class and their assistants alike are notably alcoholic. In every case this rate exceeds the general average, to an extent ranging from 22 per cent for drapers' assistants, to 142 per cent for butchers, fishmongers, etc.

Comparative mortality figures showed cancer to be excessive among fish and meat dealers; cerebral hemorrhage was likewise excessive in this group as well as diseases of the circulatory system, heart disease and Bright's disease.

Shopkeepers ran below shop assistants in tuberculosis, respiratory tuberculosis, and bronchitis, but equal to or above in all other afflictions, including suicide and accidents.—T. H. C. Stevenson (General Register's Office, Great Britain), *Med. Off.*, 1147: 26-28 (July 19), 1930.

The Silicosis Bill—

The government bill entitled the Workmen's Compensation (Silicosis) Bill has been read a second time in the House of Commons. It empowers the home secretary to make schemes to enable employers to pay compensation to work people who contract silicosis and provides for improved medical arrangements for the diagnosis and certification of the disease.

It has been found that the diagnosis requires great skill and the latest scientific appliances. The bill is intended to secure uniform and effective medical arrangements, by means of medical boards and panels in different centers, the work of which would be coördinated. It is also intended to provide for the payment of compensation for partial incapacity as a consequence of the disease in all the industries concerned. It is not suggested that all workers, who number between 60,000 and 70,000, need to be medically examined, but periodic examinations will be necessary for the early discovery and arrest of the disease before it has made progress. The bill extends compensation to workers in asbestos dust, who number about 2,200, of whom 1 in 8 have been found affected with silicosis.—

London Letter, *J. A. M. A.*, 94, 4: 277 (July 26), 1930.

Night Work and Women's Health in Japan—The Factories Division of the Urban-Prefectural Office of Osaka has made public the results of an investigation of Dr. H. Sukekawa into the effect of the abolition of night work upon the health of women workers. The study covered 1,000 women workers, from 14 to 30 years of age, living in dormitories attached to cotton-spinning factories, and covered the 5 years ending in 1930, during which night work was abolished.

Little variation was noted in the sickness rate, chiefly because workers obtained medical advice more frequently after the establishment of the health insurance system than before. Cases of tuberculosis, however, were not so numerous, and the average duration of sickness decreased. The attendance rate was 92 per cent before abolition of night work and 96 per cent after abolition. An improvement of the workers' appetites was proved by the increase of the per capita consumption of rice (10 per cent). Fatigue symptoms were found to be less in evidence.

When night work was practised, the maximum loss of weight during a week of night shifts was 3.9 kg. After the

abolition of night work, the maximum loss of weight during a week of afternoon shifts (2 p.m. to 11 p.m.) was 1.3 kg. At the same time, the number of persons who gained in weight, as well as the actual amount gained, during a week of morning shifts (5 a.m. to 2 p.m.) increased considerably.—*Indust. & Labour Inf.*, 34, 8: 280-281 (May 26), 1930, taken from *Osaka Mainichi*, 27 March, 1930.

The Best Light for Clerical Work—The National Physical Laboratory has investigated the subject of light for clerical work and made trials in some clerical offices badly supplied with natural daylight. Lights providing artificial daylight were compared with tungsten lamps.

The results obtained under laboratory conditions showed that, for equal illumination, artificial daylight was definitely preferred by clerks to light of the color of that given by a tungsten filament vacuum lamp. Light distributed over a room from an artificial window was preferred to light from a semi-indirect bowl fitting suspended from the ceiling. The average hourly rate of output of clerks showed a decided preference for light of artificial daylight color as compared with that of a tungsten vacuum lamp. Full scale experiments were then made in government offices by installing artificial daylight. Definite advantages were found when the artificial light had to be mixed with natural light, as in basement rooms. But in ordinary offices with effective window lighting, where artificial light had to be used only when natural light failed, opinions varied as to the relative merits of artificial daylight color and that of ordinary vacuum or gas-filled lamps.—

London Letter, *J. A. M. A.*, 95, 4: 276-277 (July 26), 1930.

Progress Announcement: VI International Congress of Accidents and Industrial Medicine—A meeting of the organization committee was held early in August, 1930, at which 13 were present from various countries. The honorary presidents and an honorary committee were selected, the former

comprising M. Albert Thomas of the B. I. T., Prof. Dr. Kaufmann of Zurich, Prof. Dr. Devoto of Milan, Sir Thomas Oliver, and M. Pometta.

The date of the Congress was set to begin August 3, 1931, at Geneva and to last 5 or 6 days. Membership is to be \$5.00 (in American money). The various nations are, or had been, invited to send official delegates. The exact title of the Congress was fixed for four different languages, the title hereof being that selected for the English language.

The committee for the United States so far accepted is comprised of Dr. Francis D. Donoghue of Boston, Mass., Dr. Emery R. Hayhurst of Columbus, O., and Dr. Francis D. Patterson of Philadelphia, Pa. The personnel from 15 other countries was likewise announced.—Communication from the General Secretary, Geneva, Aug., 1930.

Protection against Lead Poisoning in Germany—The German Government issued an Order on May 27, 1930, relating to the protection of workers engaged in house-painting against the risks of lead poisoning.

The order prohibits the use of white lead, sulphate of lead and products containing these pigments in the internal painting of buildings whenever the quantity of lead contained exceeds 2 per cent. It requires protective measures against the inhalation of lead dust during the work of scraping paint. It prohibits the employment of women and young persons under 18, other than apprentices and journeymen painters, and requires the provision of lavatories and cloakrooms, and the posting of a copy of its provisions and of a warning against lead poisoning therein. It also gives to inspectors the right to require a medical inspection whenever they deem it necessary, and compels the employer to provide for the medical supervision of the staff if it exceeds 5 persons.

The doctor has the right to require

any worker showing symptoms of poisoning to cease work until he is completely cured. Medical inspection on engagement is compulsory, and the workers must be informed of the risks they incur. On the advice of the doctor, any worker for whom the nature of the work constitutes a danger must be excluded from tasks involving risks of poisoning. In undertakings of a certain size the employer must keep a health register, open to examination by the inspectors.—*Indust. & Labour Inf.*, 35, 1: 54 (July 7), 1930.

Health Regulations in Bolivia—A Presidential Decree of June 3, 1929, lays down measures for the protection of the workers' health in industrial establishments in Bolivia.

The General Directorate of Health is entrusted with the control and supervision of health and safety in all the industrial establishments of the Republic without exception; it will draw up regulations regarding industrial hygiene, protective devices for machinery, lighting, ventilation and other measures for the protection of the workers against dust, vapors and industrial accidents.

A register will be kept in each industrial establishment, in which the health authority will enter observations relating to the protection of the workers' health; these observations must be complied with within a fixed time limit.

Representatives or proprietors of industrial undertakings are required to send to the General Directorate of Health a complete monthly list of sick workers, specifying the nature of their sickness, and also the names of those workers who are habitually in a state of intoxication. These lists will be considered confidential, and the General Directorate of Health may not make any use of them other than of an educative nature. In the event of industrial undertakings paying no heed to the instructions of the General Directorate

of Health, the latter will have the necessary improvements carried out at the expense of the proprietors.—*Indust. & Labour Inf.*, 34, 8: 282 (May 26), 1930, taken from *Boletin de la Direccion General de Sanidad Publico*, La Paz, Aug., 1929.

Carcinogenicity of Oils—The Manchester Committee on Cancer reports that two of the largest oil producing companies in the world have recognized the importance of discovering a safe lubricating oil at reasonable cost and are assisting the committee's staff in its investigations.

From experiments made it would appear that carcinogenic compounds begin to be formed between 500° and 600°, the maximum yield lying between 800° and 900° C. A synthetic tar containing the carcinogenic principle has been made, such that a 5 per cent solution was found to be more effective in producing cancerous growths than shale (petroleum) oil, the most dangerous commercial oil, but it has now been found possible to produce tars at least 100 times as powerful as shale oil. It was found that applying petroleum oil five times instead of two per week increased the carcinogenic potency fifty-fold.

The staff found that olive oil, neats-foot oil and sperm oil were non-cancer producing and they have reason to suppose that natural skin fat is an important factor in the prevention of experimental cancer. Thus lanoline applications alternated with synthetic tar applications delay the development of tumors. Where lanoline is applied twice as often, cancer does not appear, the protection afforded by alternate applications being much less marked.

The committee is now investigating the amount of sulphuric acid "washing" necessary to detoxicate petroleum oils and render them harmless as carcinogenic factors.—Unsigned, *Brit. M. J.*, 3615: 750 (Apr. 19), 1930.

Lead Tetraethyl in Motor Spirit—Among interesting features of the final report of the Departmental Committee appointed by the British Minister of Health, who inquired into the possible danger to health arising from the use of lead tetraethyl in motor spirit, are the following:

Though new and more refined methods for detection of lead in the urine were devised, no reason for disagreement with the results of the American inquiry was found, namely, that comparatively larger quantities were excreted by town dwellers and more still by workers exposed to special risks, excretion of lead being caused partly, if not mainly, by inhaling dust containing lead, involving a fairly close relation between the degree of exposure to lead and the proportion of lead in the urine. The average amounts found were 0.04 mg. per liter.

The lead content of settled dust in streets and garages was investigated by sampling in London and neighboring country districts, and the proportion yielded varied within the wide limits of nil to 3.3 per cent. The committee hold that the risk of chronic lead poisoning from daily inhalation of fumes over a long period is remote, the lead content of the dust in garages having been found greatly inferior to that in factories using lead.

It was likewise deemed improbable that pedestrians would inhale a dangerous quantity of lead escaping from exhaust pipes of cars during acceleration, while the risk from absorption of lead tetraethyl owing to contact of ethyl petrol with the skin is considered so slight as to be negligible.

No legislative action is advised by the committee, but special precautions are outlined to be followed by proprietors and vendors.—*Indust. & Labour Inf.*, 36, 8: 278-279 (May 26), 1930, taken from *Brit. M. J.*, 3614: 712 (Apr. 12), 1930.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Fat-Soluble Vitamin of Milk—Reference is made to the report a number of years ago of the observations that apparently fat-free milk promoted growth in animals; furthermore, that other investigators had reported a deficiency of vitamin A factor in washed butterfat, all indicating the possibility of a vitamin A factor in the milk other than in the fat.

Short-horn cows furnished the milk which contained 3 per cent fat, and 12.05 per cent total solids. The milk was concentrated at a low temperature to water content of 22.15 per cent. The separated milk containing 0.1 per cent fat was concentrated to a water content of 32.75 per cent. The separated cream was churned and the buttermilk concentrated. To determine vitamin A butter was fed in daily doses of 0.1 gm., 0.2 gm., and 0.6 gm., and in the whole milk and in the skim milk plus buttermilk vitamin A was determined by administering doses of the former approximating one-half those of the butter and in the latter mixture in amounts somewhat greater than the amount of butter given. In addition, the basal diet was fed *ad lib*.

To test vitamin D a special diet was devised and observations were made by the increase in weight produced by the addition of vitamin D in this diet, free from this vitamin but otherwise adequate. Growth curves of the animals on the skim milk plus buttermilk were more or less proportional to the residual fat present, a marked difference being noted between the minimum, 0.016 gm. residual fat, and the maximum, 0.066 gm. In the latter case the growth approximated that with 0.1 gm. of butter, in-

dicating the minimum dose of milk fat somewhere between these quantities. The same ratio of growth to butterfat content was noted in those rats fed the whole milk.

While results with vitamin D were not so satisfactory owing to the limitations of the method, the conclusion is drawn that this vitamin is associated with the milk fat since the growth promotion on the skim milk was proportional to the amount of residual fat.

The analysis of the femurs of these rats indicated the ash-organic bone residue ratio to be proportional to the amount of milk fat, the optimum being obtained on a daily dose equivalent to 0.2 to 0.6 gm. butter.

It is concluded that both vitamin A and D in milk are associated with milk fat and no more concentrated in one fraction of the fat than in another. There is no appreciable loss in either vitamin due to separating or churning.—Margaret Emily Frances Crawford, John Golding, Edith Olga Veronica Perry and Sylvester Solomon Zilva, *Biochem. J.*, 24, 3: 682, 1930.

Brucella Abortus in Certified Milk—*Brucella abortus* has been demonstrated in samples of raw milk by inoculation into guinea pigs by many investigators. Evans, however, in 1915, successfully demonstrated the organism by plating methods. Hasley has shown that *B. abortus* can be isolated from certified milk on plates by using varying amounts of milk spread on poured liver agar (Stafseth) plus gentian violet in a dilution of 1:200,000 placed in an atmosphere of 5 per cent CO₂ and incubated for 3 days at 37° C. *B. abor-*

tus was grown from 10 of the 230 samples examined. The highest number of organisms found was 8 per c.c. of milk and the average was 2 per c.c.—D. E. Hasley, *J. Infect. Dis.*, 46: 430 (May), 1930.

The Calcification of the Lung in Healthy and Tuberculous Rabbits with Large Doses of Irradiated Ergosterol—Following researches on the calcification produced by irradiated ergosterol, these authors have determined the calcium content of the lung in 4 groups of rabbits: (1) normal rabbits, (2) normal rabbits treated with irradiated ergosterol, (3) tuberculous rabbits, and (4) tuberculous rabbits treated with irradiated ergosterol.

The ergosterol in oil was administered by various means but the most advantageous was found to be through the mouth. Furthermore, doses were sought which would prove calcifying but not too toxic whether using slightly irradiated ergosterol (45 minutes) by mouth, or strongly irradiated (6 hours) by other channels.

At death the lungs of the animals were ashed and calcium determined, figures being reported on pulmonary tissues dried at 100°. Comparisons of calcium of the thoracic and abdominal aortas were included. In normal rabbits the lung calcium varied between 0.10 and 0.15 gm. per 100. In the rabbits receiving ergosterol this figure varied from 0.42 to 2.06 gm. per 100.

The rabbits were inoculated with a known type of bovine bacillus of tuberculosis. In their defense against the tuberculosis and accompanying pneumonia there was an apparent attempt to calcify the bacillary lesions, but the infection was so great as to finally carry off the animals. In the lungs of 3 which lived 50, 82, and 87 days, the calcium was found to be 0.16, 0.68, and 0.67 per 100. In the case of the tuberculous rabbits with ergosterol, calci-

fication ranged from 0.19 to 0.68 per 100 of lung calcium.

According to the figures, irradiated ergosterol in normal animals can increase the rate of calcification of the lung from 1 to 20. The tuberculous rabbit can by natural means increase by 5-fold the original calcification but with appropriate doses of ergosterol, sufficiently irradiated but nontoxic it is possible to increase this figure of lung calcium from 1 to 80.

Even though these animals succumbed to the experimental tuberculosis, attention has been drawn to the importance of calcium as aiding in a certain measure the defense of the organism. It remains to be seen if in mild or chronic cases this calcification can retard or check the development of tuberculosis.—H. Simonnet and G. Tanret, *Compt. rend. Soc. de biol.*, 190: 1526 (June 23), 1930.

Comparative Studies of the Influence of Acid-Forming and Base-Forming Diets on the Metabolism of Rats—Most of the diets recommended by pediatricians for infant feeding are calculated to be acid-forming, while the daily requirements for growth indicate a preponderance of basic elements in inorganic constituents. For this reason experiments were undertaken on the feeding of rats to determine the effect of these elements on infant metabolism.

Young rats between 30 and 35 gm. were used and were maintained on natural foods on which the acid-forming and basic elements were determined. Analyses of the blood of the two groups were made at the end of the 28th week and in addition to the pH value the inorganic radicals determined were CO₂, Cl, P, and Ca. The organic determinations included sugar, cholesterol and protein.

The result of the acid-forming diet was reduction in serum phosphorus, to-

tal alkali reserve and the pH value with a rise of chloride, sugar and cholesterol. Converse changes followed the base-forming diet.

Histological examination of bones indicated a development of rickets in the acid diet. On the base-forming diet there were no thoracic deformities, the extremities were large and firm although the cell structure showed some resemblance to rickets. Analysis of the bone indicated a preponderance of ash on the base-forming diet. Animals on the high base diet showed greater average gain in weight than those on the acid diet. Weight curves show definitely these marked changes.

The protein in each group remained constant when the pH of the "basic" animals was on the alkaline side and of the "acidic" animals on the acid side of 7.4. The fat content in its degree of unsaturation as evidenced by the iodine number apparently was uninfluenced by the proportion of acid and base element. The fact that base-forming foods increased the weight while an opposite result obtained with an acid diet is discussed on the theory of the electro-negative charge of the protoplasm at pH 7.4, requiring for its maintenance in solution electropositive ions. While definite conclusions could not be made in the case of infant feeding as a result of

this experiment evidence seems sufficient to warrant a consideration of these principles in practical infant feeding.

It is probable that a mineral deficient diet such as is found in refined cereals may be compensated by adding fruit and vegetable juices and as a defense against rickets the basic diet favors the retention of calcium and phosphorus. Basic-forming food is also an advantage in correcting the acidosis due to acute infections and gastrointestinal disturbances.—Emma Louise Samuel and I. Newton Kugelmass, *Am. J. Dis. Child.*, 39: 687 (Apr.), 1930.

On a Possible Preparation of a Highly Active Ergosterol (Vitamin D) from Raw Coffee—A substance can be obtained from raw coffee and in very small amount from roasted coffee as a constituent of the unsaponifiable matter of the fat, which gives the spectrum of active ergosterol. The substance loses its activity in several weeks. On rats made rachitic by McCollum's diet, 3,143 therapeutic and prophylactic studies showed the ergosterol to have curative and protective properties. The article includes technical comment on the handling of experimental animals for Röntgen photography.—L. Schwarz and F. Sieke, *Arch. Hyg.*, 104: 65 (Aug.), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Who Is a Public Health Nurse?—
The *Board Members' Manual* gives the following definition of a public health nurse:

The term public health nurse applies to any graduate nurse who is taking part in an organized community service to individuals and families, including the interpretation and application of medical, sanitary and social procedures for the correction of defects, prevention of disease and the promotion of health, and may include skilled care of the sick in their homes. Formerly, the term "visiting nurse" referred to the nurse whose chief activity was bedside care, and "public health nurse" to the nurse whose principal efforts were educational. The term public health nurse, however, has come to include both groups of nurses, and is so used in this manual.

In the *New York State Health News* for July 7, 1930, a few outstanding points about the public health nursing movement, prepared by Ada Newman of the Wisconsin State Board of Health for the U. S. Public Health Service, help to explain several phases of public health nursing:

Public health nurses are found in large numbers in the original task of caring for the sick in their own homes. These nurses are graduates of 3-year hospital training courses and were either taught visiting nursing by the staff school or took a postgraduate course.

The next largest service of the public health nurse is that of school nurse. She assists the health officer in communicable disease control, aids the school physician in examination of school children, and makes home visits to interpret the findings and advice of the physician to the parents.

Public health nursing is recognized not only from a humanitarian point of view and as an educational force, but also on the basis of com-

mercial value. This is demonstrated by the fact that business concerns employ nurses in large numbers, believing that in order to have their plants operate on a more efficient basis, the health of the employees and of their families should be protected. Insurance companies also employ many nurses to work among their policy holders. When we consider that the only motive back of industrial nursing is a financial saving for the employing body, it speaks very highly for the economic value of such service.

The latest nursing activity to be developed in the United States is rural community nursing. These rural programs are planned to cover in part health educational work for the adult and for the school child, infant welfare, and the prevention of communicable diseases; in short, all phases of nursing service.

Mary S. Gardner's book *Public Health Nursing*, which is recognized as the standard textbook on public health nursing the world over, has listed in the table of contents under "Special Branches of Public Health Nursing" the following: Tuberculosis, Child Care, School, Mental Hygiene, Industrial, and Venereal Disease.

The National Organization for Public Health Nursing, with headquarters in New York, is recognized as the standard making body in the public health nursing field. It is a member of the National Health Council and advises and assists the American Public Health Association through its Committee on Administrative Practice in matters of policy and administration, and in field studies where public health nursing is concerned. This organization has industrial, school, tuberculosis and social hygiene specialists on its staff, and has been mainly responsible for the great number of visiting nurse associations

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

which have sprung up in this country since its establishment in 1912.

It might almost be said that any graduate registered nurse who is doing nursing other than institutional or private duty nursing, or who is a physician's office assistant, is a public health nurse, and Annie Goodrich says that every graduate nurse should be a public health nurse in that she teaches health to the public.

Supervision—A very good definition of supervision is that made by Fannie Dunn of Teachers College: "Instructional supervision has the large purpose of improving the quality of instruction, primarily by promoting the professional growth of all teachers, and secondarily and temporarily by correcting deficiencies of preliminary preparation for teaching by training teachers in service."

Supervision does four things:

1. *Inspection*—The old idea of supervision was inspection alone. It was catching the worker and watching his deficiencies.

Today inspection is still necessary in supervision to gather the facts, "to know the situation, particularly the weaknesses, deficiencies and possible betterments."

2. *Training*—If this is to do any good there needs to be a definite program for it over a definite period of time. Inspection reveals what the nurses need, and training is definitely directed to the supplying of these needs.

A training program should be two-fold. The aim is to improve the worker in the direct performance of his everyday work, and also in a more general way by means of suggesting supplementary reading and by organizing conferences.

3. *Guidance*—By this is meant that the better teachers are stimulated to experiment, and to help plan the program of supervision by giving the supervisor practical suggestions. They are also inspired to "look for promotion, and further training and advancement." This implies "developing and maintaining morale, professional spirit, *esprit de corps*." Since it takes great leaders to bring out more than average work among the workers this development of morale is one of the finest contributions the supervisor can make to her staff.

One of the methods of developing this mo-

rale is to "maintain a personal attitude which is fair, sympathetic, kindly and tolerant." Another method is to help willingly and happily when help is needed. The last way is for the supervisory staff to know their stuff so they *can* help.

4. *Research*—A good supervisor should be open minded enough to be willing to try out new things in order to find better ways of doing the work in hand.

There are four other points which show the contrast between the new and the old supervision:

1. The new supervision is continuous, not piecemeal, and is not confined to visiting and conferring with the worker himself.

2. "Traditional supervision was inspection. Today it is help and assistance and encouragement."

3. The old supervision was done by one person. Today good supervision implies several different supervisory contacts just as several judges are better than one.

4. "Supervision today is not authoritarian. It develops out of the need of the workers under supervision." There are several reasons why the new supervision has come into use:

a. "It is an accepted business principle in many business corporations."

b. "The average worker in any field is not a highly trained individual," and needs supervision to move towards the ideal.

c. Even a highly trained worker cannot keep up with the new developments in the field. "She has to have an agency, a supervisory staff which reads, digests, and corrects the new material to the level of the classroom worker."

W. H. Burton, Ph.D., *Supervision, Am. J. Nurs.*, XXX, 8: 1045-1051 (Aug.), 1930.

Every public health nurse will know on reading this article that although Dr. Burton speaks from the point of view of a teacher, every point he makes applies perfectly to supervision in public health nursing, because every public health nurse is a teacher. There has been a great deal said and written the last few years about staff education in every public health nursing organization. And surely any one getting these points in Dr. Burton's paper will see the need of staff education and the opportunities that it presents, both to the supervising nurses and to the staff.

For School Nurses—Scales have a very definite part to play in the school health program as an educational means of interesting children in health and health practices. Emphasis is now placed upon gain in weight instead of on underweight status. A child failing to gain for several months is abnormal and should receive medical attention.

Several studies have brought about this shift of emphasis. The Massachusetts State Department of Public Health found after examining 50,000 school children in that state that one-third of the children who were pulmonary cases were not underweight, and one-fifth of the latent tuberculosis cases found in the contact group were in normal or overweight children. They concluded that children exposed to an open case of tuberculosis are infected with the tubercle bacillus to the same degree regardless of nutrition or nationality.

Dr. Raymond Franzen of the American Child Health Association after a school health study concluded that height is insufficient skeletal information to use as a basis of weight classification.

The Massachusetts State Department of Health in their 10-year program for discovering children with some evidence of tuberculous disease now give all children a tuberculin test, and those who react positively are X-rayed. If the X-ray film shows evidence of tuberculosis or other pulmonary conditions the child receives a thorough physical examination by the state physician. In this way it is estimated that 50 per cent or more of tuberculosis cases in adult life can be picked out of the 10 per cent of children who are shown by the X-ray to have been infected.—Louise Strachan, *What Do Scales Weigh? School Life*, XV, 9: 178 (May), 1930.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

An Attractive Annual Report—The 1929 report of Palama Settlement of Honolulu is unique. The pages are in groups of three different sizes and bound terrace fashion, each "terrace" dealing with one phase of the work, namely, Community Service, Nursing and Medical, Recreation. Several of the statistical tables are presented in the form of ingenious picture graphs. Line drawings brighten most of the pages. The chapter "One Day with a

Palama Health Nurse" sketches a typical day's experience from 8:00 A.M. to 4:00 P.M., which is an excellent way of visualizing for the layman a more or less intangible service. Philip S. Platt is director of Palama Settlement.

Quackery and the Spotlight—Modern health education, with its emphasis on the positive aspects, is supposed automatically to neutralize ignorant deductions and false teachings. Yet it is the interest created by legitimate health education that feeds the quacks. A direct attack on chicanery is a part of health education.

Health Commissioner Shirley W.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y., who will return from Europe in time for the November JOURNAL. Dr. H. E. Kleinschmidt has been in charge of this department for September and October issues.

Wynne of New York City undertook some months ago to rid the radio of medical and health swindlers. Through the coöperation of local radio stations, he succeeded admirably, but local restrictions curtailed his ambition to sweep clean. Therefore, he advocated the compilation of an "Index Expurgatorius" for the guidance of broadcasting stations everywhere and appealed to the National Better Business Bureau for help. That organization, after more than 6 months' labor, classified a "Rogue's Gallery" of some 25,000 medical quacks, nostrum manufacturers and peddlers, diet inventors and other vultures.

The mellow, lifegiving sunlight of health education needs to be supplemented by the harsh spotlight of pitiless publicity.

When Is an Exhibit?—Every summer national health agencies receive appealing letters saying "I have been allotted space for a health exhibit at Blank County Fair. Please send me some good material." Generally Oscar, the office boy, mechanically rolls up an assortment of posters and sends them on. In due time these find their way to the booth with sundry unrelated posters elbowing each other for breathing space. But nobody cares!—except the genial chairman who says the exhibit is "nice."

According to the *Ohio Health News* of August 15, 1930, the Ohio Department of Health intends actually to "exhibit" its work at the state fair. Each departmental division is preparing a unit designed to tell John Jones what that division is doing and how it touches his life. For example, the unit on Roadside and Camp Sanitation will consist of models showing the proper installation of power and hand operated pumps. Experienced attendants will be on hand with a specially prepared pamphlet on the work of the depart-

ment. We assume that the mosaic will be put together by a skilled showman, and we hope the effort will demonstrate what a real exhibit can be.

Precept Plus Example—A certain school principal insisted on serving coffee in the cafeteria in preference to milk because it was more economical. Meantime, the teaching staff were daily emphasizing the virtues of milk. So writes Dr. Phair, chief school medical officer of Ontario, who pleads for better correlation between preaching and practice. The best way to stimulate actual interest in personal health in the pupil-teacher is to provide a well rounded system of health service in the normal school. Such service improves the health of the future teacher and "carries with it the conviction of practicability." In addition, of course, the normal school should offer thorough training in the principles of health and the technic of teaching these principles. Dr. Phair's article, "Health Teaching in Normal Schools," was published in the *Canadian Public Health Journal*, May, 1930.

A Health Text Book—The Milwaukee Health Department issues an alluring textbook on "Home Hygiene and Care of the Sick," which is used to supplement class periods conducted by the department at social centers, settlement houses, and schools. Each of the twenty lessons is preceded by a brief statement of its aim and followed by a number of provocative questions. The instructions given are simple and practical. If bits of useless knowledge, such as how to make a mustard plaster or the advice that the sick attendant should not wear jewelry, seem to burden the book, that may be charged to this guest editor's harmless prejudices.

The book elicits comment in these columns because it is a very creditable home-made job. It was printed in the health department office by multigraph.

The sheets are of letterhead size on very heavy yellow-tinted stock. Only one side of the sheet is printed. This makes the book somewhat bulky. The sheets are bound with metal staples and covered with a cardboard stock of soft, marble-like tones.

It would be interesting to learn how the cost of production of this booklet would compare with a professional printing job. Its individuality, however, gives it a value which would be difficult to appraise. The Milwaukee Health Department offers a limited number to our readers free of charge. Write early.

The Milwaukee Health Department also prints in the same style a smaller manual on preschool clinics. Here both sides of the sheet are printed. The type does not press through and the effect is very neat. A limited number of copies free for early askers.

Jazz Typography on the Skids—J. L. Frazer, whose typographic judgments are recognized to be authentic, has for some time swung his cudgel against "modernism" in type. He uses the term in its commonest meaning; i.e., synonymously with "jazz," and believes the wave of bizarre typography in advertising is receding. *The Inland Printer*, of which Mr. Frazer is editor, restates in its August, 1930, issue eight typographical abominations which every user of type should shun:

1. Illegibility through the use of overblack and complex faces of type
2. Ugliness from the use of eccentric types
3. Ugliness through the combination of unrelated forms constituting an assault on common good taste
4. Geometrics as commonly applied in layouts and as also indicated in the excessive use of black patterns of varied shape which dis-

grace the name "ornaments" and keep the mind off the message in type

5. Excessive and excessively heavy rule work that, like other jazz features, tends to increase the cost of composition while placing a handicap upon readers which most of them will not attempt to overcome

6. Setting lines aslant, in curves, and vertically, instead of horizontally, as they are read

7. Illustrations which, like much modernistic typography, must be studied out

8. Composition sans capitals which disregards the part they play in denoting important words and making print more readily comprehended

Let the health publicist who creates printed matter and prescribes type and layout take notice!

Good Ideas—For a sample of attractive mimeograph work see the *Bulletin* of the Middletown (N. Y.) Board of Health. The July, 1930, number is a model of neatness and attractive arrangement. The illustrations are apt and exceptionally well done. It was prepared and mimeographed by Mildred Gillistin.

"My Daddy is the Health Commissioner" is the head line of a little poster illustrated by a series of six portraits of a charming little miss who tells how and why she was protected against diphtheria. It is issued by the Racine Department of Health. The department also uses a milk bottle collar as well as folders promising the people that "we are going to knock out diphtheria." Samples of this material may be obtained by applying to Dr. W. W. Bauer, Commissioner of Health, Racine, Wis.

"Early Diagnosis or Early Grave."—*Health Briefs*—Tenn. Dept. of Health.

BOOKS AND REPORTS

Harvey W. Wiley. *An Autobiography—Indianapolis: Bobbs-Merrill, 1930. 339 pp. Price, \$5.00.*

The recent death of the author at the ripe age of 86 years adds interest to his life story. He was born on a farm in Indiana, received his early education in the "old log school house," served in the Indiana Legion during the Civil War, later entered Hanover College, and finally graduated in Medicine from the Indiana Medical College in 1871. During his studies he discovered a special liking for botany and chemistry. A year after graduation he became a teacher of chemistry in his Alma Mater, and to prepare for this task, went to Harvard, where he came into contact with some of the great men of that time. For 9 years he taught chemistry at Purdue University, during which his interest in foods, their relation to health, and their adulteration increased steadily. In 1883, he went to Washington as Chief of the Bureau of Chemistry in the Department of Agriculture, a position which he held for 29 years.

Dr. Wiley's life was full of interesting events, but he will always be best known on account of the strenuous and prolonged struggle he made for the betterment of foods and the prevention of adulteration. This brought him into conflict with certain presidents, vice-presidents, cabinet officers, and appointed officials, to say nothing of the number of manufacturers who sought for years to get his scalp. The history of his fight for pure foods is one of the most heartening in the scientific annals of our country, and the part played by administrative officers, from certain presidents down the line, is one of the most sickening. Finally, Mr. Wickersham, then Attorney-General under

President Taft, and now chairman of one of Mr. Hoover's many Boards, made charges against him of having conspired to defraud the government, and certified to President Taft that he was worthy of dismissal and "condign punishment." He was completely exonerated, and it will always be to President Taft's honor that he supported Dr. Wiley in his protection of the public.

He married when he was 66, and soon after, 1912, resigned from the Service. The union was blessed by two sons. The later years of his life were spent in giving public addresses on the Pure Food Laws, and doing editorial work for *Good Housekeeping*.

Dr. Wiley will always be known as a friend of the people and the Father of the Pure Food Laws of our country. It is interesting to note that almost coincident with his death, there is a scheme on foot by the present Secretary of Agriculture to allow adulteration with corn sugar without the fact being stated on the label.

The book is written in interesting style, and with the volume by the author which preceded it by a short time, *The History of a Crime Against the Food Law*, should be in the library of everyone who is interested in nutrition.

M. P. RAVENEL

Infant Nutrition. A Textbook of Infant Feeding for Students and Practitioners of Medicine—By *Williams McKim Marriott, B.S., M.D.* St. Louis: Mosby, 1930. 375 pp. Price, \$5.50.

Proper nutrition is essential to good health at all ages, but it is particularly important in the crucial first years of life. Infant mortality is diminished when babies are competently fed with

pure milk products, administered by informed mothers under the direction of skilled physicians. This book should do much to assist practitioners in acquiring the scientific principles of infant nutrition. Out of an extensive clinical experience the author has produced a thorough, clearly expressed, logically arranged, and well illustrated work, which seems to contain all of the salient details regarding the feeding of well or sick infants.

In the 34 chapters of this book, the fundamental principles of infant feeding, such as the proper employment of the fats, proteins, and carbohydrates, the function of the vitamins and minerals, the technic of breast feeding, the requirements for artificial feeding, and the character of materials, are all set forth. An entire chapter is devoted to evaporated milk, and another to acid milk, both of which are much favored by this writer. Various physical disorders such as diarrhea, malnutrition, vomiting, colic, constipation, rickets, and other afflictions are also completely discussed in the various chapters.

This modern presentation of an important phase of public health ought to be of value to health officials and physicians who are directly concerned with baby clinics and infant feeding problems.

JAMES A. TOBEY

Die Statistischen Methoden. (Statistical Methods)—By *Karl Freudenberg*. Berlin and Vienna: Urban and Schwarzenberg, 1930. 558 pp.

This is one of a series of handbooks on method in biology, edited by Dr. Emil Abderhalden of Halle. It deals with descriptive and elementary analytical methods in medical statistics. Hence, on the side of subject matter, it includes what is commonly understood to be demography or vital statistics, some anthropometry, biometrics, certain branches of welfare economics, and other disciplines which do not ordinarily

find their way into the existing texts available to our American students.

The elementary analytical-mathematical methods described by Dr. Freudenberg are drawn from the literatures of England, Austria, Germany and the Scandinavian countries. There is even a short, but satisfactory, description of the major methods and results of life, health and accident insurance statistics.

Because of its comprehensive scope the work should serve as an excellent first book for students of vital statistics. In many of the chapters, Dr. Freudenberg has brought his data down to 1928. The bibliography includes the accessible and pertinent texts on medical and social statistics in the German language. Unfortunately, the table of contents and index will not be available until the other parts in the hygiene handbook of the series are bound. A few descriptive table headings would have added to the usefulness of the book. Table heading technic seems to be faulty in most German and French statistical texts. Dr. Freudenberg has recently contributed to the *Journal of the German Society for Insurance Science* an attractive article on "Statistics and Causality" (March, 1930). Vital statistics and the personal insurances seem to be more closely allied in Germany than in other countries.

If one agree with certain Europeans that statistics is the art of reaching clear and profound conclusions from numerical data pertaining to a given field of interest, and gathered for this purpose (*Carl Burrau* in "Grundzüge der Versicherungsstatistik"), then Dr. Freudenberg's book promises to reward the student with an understanding of elementary "statistical method."

The text is not difficult to read, and the publisher has provided an attractive Roman type face. The book should find readers among vital statisticians in the United States; in a sense, it will be found to have antidotal properties.

E. W. KOPF

A Textbook of Hygiene—By J. R. Currie. New York: Wood, 1930. 844 pp. Price, \$8.50.

We owe to England the great modern awakening in public health, and in many respects she still leads us in this branch of medicine. English books have some drawbacks for American readers, but the fundamental principles of hygiene are always the same, their application being modified by the surroundings. Therefore, one can read English books with pleasure and profit.

The aim of the author has been to meet the requirements of students in hygiene and public health under the medical curriculum, and at the same time to assist candidates in Parts I and II of the examination for the diploma in public health or degrees in sanitary science. We believe that he has succeeded in fulfilling his object in an unusually good manner.

Each section is followed by a statement of the legal enactments involved for England, Scotland and Wales. These laws do not interest the American reader particularly, though they may well be studied by our health authorities, and in many instances imitated. While the author distinctly disclaims any attempt to deal with the whole domain of hygiene, or to cover the field of modern public health administration, he has in an excellent fashion selected the important points for the students especially, but also for the practitioner who wishes to keep posted on the modern advances in sanitary science.

All of the subjects usually covered in such a volume are taken up in order and adequately treated. The sections on Food, Infectious Disease, and Helminthes, Insects, and Arachnida, are especially good. There is also an excellent section on Port Sanitary Administration, which has always been of especial importance to England on account of its enormous shipping and the significance of which has increased in all

countries with the passing of the sailing vessel and the substitution of steam.

The book can be thoroughly recommended as one of the best in its class. The illustrations are abundant and good, and the printing and general make-up excellent.

M. P. RAVENEL

Essentials of Pediatric Nursing—By Ruth Alice Perkins, R.N. Philadelphia: Davis, 1930. 364 pp. Price, \$2.75.

The material in this book was arranged to meet the requirements of the course in pediatric nursing suggested by the National League of Nursing Education in the last edition of the curriculum.

Because of increasing interest in the study of the normal child, orthopedic and communicable disease nursing are omitted—since these are now given in separate courses—and extra time is devoted to principles of child psychology and to the care of the normal child.

There is an excellent bibliography, and questions and problems, brief but to the point, at the end of each chapter which a busy teacher will greatly appreciate, as she will also the Teaching Supplement in the back, which gives outlines of courses to be given by the supervising nurse or medical staff or both. As Joseph Brennemann, M.D., says in the foreword, the book is "safe, sane, and sound."

The typing is somewhat pale, but the material is well arranged with good topical headings. The illustrations are fairly plentiful and good, some of them in colors.

EVA F. MACDOUGALL

Man vs. Microbes—By Nicholas Kopeloff. New York: Knopf, 1930. 311 pp. Price, \$5.00.

To encompass within a volume of moderate size a comprehensive knowledge of all those minute forms of animal and plant life which are correctly but too seldom termed "microbes," and to do this in a style which shall be so en-

gaging that the popular mind will be instructed while being entertained, is the difficult task which the author has set himself.

How well he has succeeded will be a matter of opinion, for there will be some who will feel that science binds itself awkwardly to the particular kind of treatment which is here employed. Not every one wishes the modernistic method.

The title and some of the text suggest that man is at perpetual war with the microbic world, but there are places in the book where the author is at pains to explain that this is not so and that, in fact, some microbes are very useful while others are indispensable, that without them human life on the earth would be entirely impossible.

Where the matter has not been touched up to make it striking or amusing it is admirable. The author has taken a great deal of trouble to bring so much intrinsically interesting and useful information together.

A book of this scope is needed by every health officer. Schools and public libraries ought to have it. It will broaden the minds of those who read it, for its scope is broad. It is crammed with the knowledge with which man's relations with the microbes, good and bad, are carried on.

He who wishes to get the latest and best facts about the infectious diseases in the making of beer and wine and bread will find the book useful.

G. A. SOPER

A System of Bacteriology in Relation to Medicine—Volume II—By C. H. Browning, W. Bulloch, J. H. Dible, A. Fleming, F. Griffith, et al. London: His Majesty's Stationery Office, 1929. 420 pp. Price, \$6.00.

Volume II of this 9-volume *System of Bacteriology*, sponsored by the Medical Research Council of England, deals with the cocci and the hemophilic bac-

teria. The first 5 chapters include the staphylococcus, the streptococcus, the pneumococcus, the gonococcus, and the meningococcus. Chapter 6 is devoted to the influenza group of organisms, while chapter 7 is a short presentation of whooping cough and *Bacillus pertussis*, chancroid and *Bacillus ducrey*i, conjunctivitis, *Bacillus lacunatus* and other organisms.

In general, each chapter covers: history, morphology, cultivation, biochemical reactions, vitality, distribution, pathogenicity, resistance, classification, and treatment. The organization is such as readily to permit assimilation of facts.

One hundred and thirty-four pages are devoted to the streptococci. They are presented under four main divisions—the hemolytic, the mouth, the bowel, and the anaerobic streptococci. An excellent table is given which summarizes the characteristics by means of which the mouth streptococci can be differentiated from other streptococci and the pneumococci. The diseases related to streptococcal infections are presented.

One feels grateful for the clear presentation of the confusing literature on the serological races of pneumococci. The account of the serums, vaccine, and chemotherapy of pneumonia gives the present incomplete knowledge of their efficacy, and the problems still to be solved before definite conclusions can be reached.

The chapter on the influenza group of organisms, of which *B. influenza* (Pfeiffer) is the most important member, includes those organisms which require for permanent cultivation on artificial mediums accessory substances present in blood and in fresh vegetable tissue. After discussing the etiology of influenza the author concludes:

It is obvious from all that has been said that, at present, the diagnosis of influenza by bacteriological methods has no sure foundation. Neither the apparent absence nor the

finding of the influenza bacilli in the respiratory passages gives an unequivocal answer (p. 374).

Each chapter includes a good bibliography. This volume will be of great value to the student and research worker as well as to the practitioner who desires to remain correctly informed as to the bacteriological advances that have been made concerning these organisms in recent years. ESTHER W. STEARN

Military Preventive Medicine—*The Army Medical Bulletin, No. 23*—By George C. Dunham, M.D., Dr.P.H., Major, Medical Corps, U. S. Army. Medical Field Service School, Carlisle Barracks, Pa., 1930.

The fundamentals of hygiene and preventive medicine are, of course, the same under all conditions. The medical officer in an army camp suffers from certain disadvantages, but is in some ways much better off than his brother in civilian life. On the other hand, we have large numbers of men, drawn from extensive areas, rapidly brought together, bringing with them various contagious diseases from the many sections which they represent. The military officer is more or less independent of local laws, and has absolute control, though sometimes hampered by long-distance, machine-made regulations issued from Washington by some incompetent swivel chair endurance sitter. While the contact is often much more direct and more close than in civilian life, control is more easily carried out.

The great point which is emphasized by a book such as the one before us is that all officers of the Army, medical as well as line, and the people in general have come to realize that the Medical Service of the Army is the agency upon which its efficiency largely depends. During the World War this was impressed on everyone. The saddest failure of England was the Mesopotamian campaign, in which the chief medical

officer was overruled and even threatened with court-martial by the line officer in command. At present, the medical officers of the Army are the most trusted consultants of the commanding officers.

The volume before us, consisting of 1,000 pages, exclusive of the index, which is good, is proof of what has just been said. It is written to provide the officers of the Medical Department of the Army with information which will assist them in their inspection and studies, and in carrying out measures to protect and promote the health of the troops. Especial attention is given to the epidemiological factors which exist among troops and to the environmental features met with under Army conditions.

Though the author states that he has made no attempt to cover the entire field of preventive medicine, it may be said that there are few subjects which have been left unconsidered. The disposal of garbage and human excreta of all kinds necessarily occupies considerable space, and excellent illustrations of the various types of emergency incinerators, folding and transportable receptacles, and knockdown latrine boxes are given.

The section on the control of vermin and insects is especially full and practical.

The book can be commended without reservation. The product shows that no better man than the author could have been selected for the task. Medical affairs in the Army advanced tremendously between the Spanish-American War in 1898 and the World War in 1917. Except for the epidemic of influenza, our Army showed a record which has never before been equaled in the world. The control of all diseases about which we had adequate knowledge was nothing short of marvelous.

The book is published by the government and is, unfortunately, not for sale. It is to be distributed to officers of the

Army, leading journals, schools and libraries in the United States. We wish that it could be put on general sale.

M. P. RAVENEL

Children at the Crossroads—*By Agnes E. Benedict. New York: Commonwealth Fund, 1930. 238 pp. Price, \$1.50.*

Here is a book that will be of interest both to the optimist and to the pessimist. The one will see in it what can be accomplished by painstaking, resourceful effort in rehabilitating children who, for one reason or another, are on the wrong track; the other will be impressed by the time, the effort and money that must be expended to bring about the desired results.

Which of these two points of view is the sounder is, of course, a matter of opinion. There is no doubt, however, that this readable story of results accomplished by rural visiting teachers working under the Commonwealth Fund grant will stimulate thought on the part of all interested in the development of agencies to deal with the misfit child.

It will undoubtedly occur to the unregenerate while reading this book that much time could be saved if public opinion were not so slow and squeamish about dealing with the worthless parent, as in the case of Tim Noonan.

On the other hand, the thought may occur to those interested in administrative matters that much of the work of the visiting teacher as depicted here might well be that of the visiting nurse, the mental hygienist, or the social worker. Are we developing many different agents to do work which might well be done by one with a little adjustment in training?

I have said that this is a readable book; it is. A sufficient number of case histories are used to give vividness to the application of general principles to the specific problem of salvaging misfit children. "Getting Caught" sounds

like the title of a thriller but its application is found in a discussion of Community Factors in Maladjustment. Other chapters deal with The Rural Child at Home and in School, Visiting Teacher Work in a Rural Setting, and Group Work in School and Community.

A commendable feature of the book is its frankness; it discusses failures as well as successes.

MERRILL E. CHAMPION

Science in the Service of Health—*By Elliot R. Downing, Ph.D. New York: Longmans, Green, 1930. 320 pp. Price, \$2.00.*

This is one of Longmans' School Science Series, edited by the author of the present volume. It is one of the many books written by laymen which have appeared during the past few years on subjects which are largely medical.

Practically it may be divided into two parts, the order of which, in our judgment, would better have been reversed. Six chapters are devoted essentially to bacteriology and its effects on the welfare of mankind. The remaining six chapters are given largely to the human body and its functions, but include such discoveries as the vitamins, insulin and the effects of the endocrine glands. An appendix is devoted to demonstrations to which reference is made in the several chapters.

The book is written in popular language; the facts are correctly stated; and a great deal of interesting history is given. There are some unfortunate misprints, as Detafond for Delafond, and Finley for Finlay. Some of the most interesting histories, like that of anthrax, for example, which was the first germ ever proved to be the cause of a disease, and the study of which has taught us much about bacteriology, are inadequate.

In general, the book belongs to the better class of its kind. The printing is excellent.

M. P. RAVENEL

History of Haitian Medicine—By Robert P. Parsons. *New York: Hoeber, 1930. 196 pp. Price, \$2.25.*

The medical history of Haiti since the American Occupation in 1915 vies with the history of the U. S. Army as an object lesson in what modern preventive medicine can do. This beautiful island, "The Flower of the Antilles," has been blessed in almost every way by nature, but was exploited by man with little regard for anything else than profit for many years. Slavery existed in the island for 292 years, during which every type of disease found in Africa was brought in and found there a suitable soil. There came also African superstitions, like voodooism, which hindered rational prevention.

Practically everyone in the rural population has suffered from malaria, yaws, and intestinal parasites. The Caribs disappeared during the period of exploitation by the Spanish, within 60 years; many of them were worked to death, many murdered outright, but most of them died from smallpox—some 200,000 within 10 years of the landing of Columbus in 1492.

Independence came to the island in 1804, at which time the French commanding general died of yellow fever, and the disease caused such ravages in his army that it was virtually defeated by that disease. Smallpox is apparently the only disease which was not introduced from Africa. This was brought by the whites.

Yaws, "the blood brother of European syphilis, if not the same disease modified by age incidence, social environment, and racial difference," was the great physical curse of Haiti, and until the advent of Dr. Wilson in 1922, its significance does not seem to have been recognized by anyone. Dr. Wilson insisted that the first need of rural Haiti was "soap, salvarsan and sunshine."

The National Public Health Service

of Haiti was organized by Captain N. T. McLean (M. C.), U. S. N. Others, like Drs. Laning, Ebert, Wilson and Butler, played a leading part in the redemption of the island. Among the Haitians, Drs. Dehoux and Audain deserve especial mention.

The author has performed his task in an unusually good fashion. The book reads like a novel. Apart from its inherent interest in telling of the redemption of a worthy people from disease, it should be in every medical library, and constantly quoted as an outstanding example of one of the great triumphs of modern medicine.

M. P. RAVENEL

Personal Hygiene for Nurses—By Seneca Egbert, M.D., Dr.P.H. *Philadelphia: Davis, 1930. 347 pp. Price, \$2.50.*

This book is written for student nurses to be used "at the beginning of their course in the training school." However, it is not so closely tied up with nursing that it could not be used just as profitably by college freshmen.

The book is sane and sound, and Dr. Egbert's approach to personal hygiene in Chapter III where he treats of the care of the body in its relation to the importance of an attractive personality is especially to be commended. The esthetic always has a strong appeal in presenting this subject to young women. Here charm is discussed from the point of view of posture, skin, cleanliness, bathing, the hair, and the teeth.

In later chapters on The Heart, Respiration, Excretion, Senses, Organs, etc., the author gets rather technical and uninteresting. Much more space seems to be given over to anatomy and physiology than to the details of personal hygiene as they apply to nurses.

In the chapter on "The Nurse as a Teacher" most public health nurses would smile at the paragraph in which the author says, "There are, however,

other branches of the profession than only that of the private nurse. Thus we have the school nurse, the public health nurse, and the industrial nurse." He evidently looks upon the rural or county nurse as the public health nurse, when he should include the school and industrial nurse as well in this category. Nothing is said about the additional training necessary to fit a graduate registered nurse to be a well qualified public health nurse.

An excellent series of questions follows each chapter and also a brief bibliography. EVA F. MACDOUGALL

The Bureau of Home Economics. Its History, Activities and Organizations—By Paul V. Betters. Washington, D. C.: The Brookings Institution, 1930. 95 pp. Price, \$1.50.

This belongs to the Service Monographs of the United States Government, No. 62. "The Brookings Institution—Devoted to Public Service through Research and Training in the Humanistic Sciences"—was incorporated on December 8, 1927, its first purpose being to aid constructively in the development of sound national policies, and the second to offer training of a supergraduate character to students of the social sciences.

The many bureaus of our national government and their overlapping have been the subject of many discussions, political as well as otherwise. The Brookings Institution, the full history of which cannot be here given, has been of notable service in telling the people of the country what is going on in Washington in the many bureaus and departments located there.

The Bureau of Home Economics was established July 1, 1923, before which many of the activities it now carries on had been administered in the Department of Agriculture. In the 7 years of its existence, it has grown from a small

investigational unit with a staff of 4 or 5 persons to an organization employing 71, and the appropriations have increased from \$71,760 in 1924, to \$167,500 in 1930.

As this is a concise and detailed description of the activities of the bureau, a review is hardly possible. The chief activities are Food and Nutrition Investigations, Textile and Clothing Research, Textile Utilization and Maintenance Work, Sewing Survey and Garment Fitting Study, and Economic Studies. An appendix gives the publications which have been put out from the bureau.

The study is wholly descriptive in character, and no attempt has been made to subject the facts to criticism, nor to indicate changes which might be made with advantage. The object is to enlighten the public and legislators as to actual facts—and as such, the book can be commended. M. P. RAVENEL

Psychology for Executives—By Elliott Dunlap Smith. New York: Harper, 1928. 262 pp. Price, \$3.50.

An interesting introduction by Henry S. Dennison of the Dennison Manufacturing Company, Framingham, Mass., where the author is Division Manager (he is also a Lecturer at Harvard University), states that learning how to manage men and how to work with them so as to get the best there is in them is of first importance to business men. The book is claimed to deal with psychology in the spirit of the engineer, and the author was a manager before he became a psychologist.

Seven chapters compose the body of the book:

I. Why Men Are and What They Are—the capacity of mankind to learn, how much is inborn and how much acquired, with a valuable discussion of "intelligence tests," and how far "human nature" can be changed.

II. Habits and How to Handle Them—developing by chance or by choice, with an

elaboration of ten precepts on correct habits.

III. Habit and Thought—memory and how to train it, the power of association, attention, etc.

IV. The Forces of the Personality—its multiplicity.

V. The Problem of Self-Control—rebellious desires, self-deception—"I am doing as much as I am paid for"—self-respect, inner conflicts and outraged desires as employment problems.

VI. The Effect of the Group in Industry—an interesting discussion of whom to advance or transfer, industrial strife and fears, and the problem of discipline.

VII. The Integration of Conflict and Methods of Analysis.

There is an Appendix on suggestions for studying and teaching practical psychology in which the author advocates the problem method rather than lectures, assigned readings, and tests. Also, an Appendix on "Good Books on Psychology" with a brief characterization of each.

To one interested in employment and personnel problems this book is highly instructive, easy reading, and filled with many practical features gained from experience. It is indeed an industrial

psychology developed out of successful management. EMERY R. HAYHURST

Hitch-Hikers—By W. W. Peter, M.D., Dr.P.H., and Grace T. Hallock. New York: Cleanliness Institute, 1930. 56 pp. Price, \$.20.

This is a small, elementary textbook on the communicable diseases entering the body via the mouth and nose. The idea of the germs of disease being passengers, on most of the objects in use in daily life, is maintained throughout, thus justifying the title.

Careful details are given of the possibilities of contagion through air, solid food, water, milk and incidental routes, each subject being treated in a separate chapter with a convenient summary at the end. Emphasis is constantly laid upon methods of disease prevention.

The booklet is well printed and profusely illustrated with photographs and diagrams, and should be a welcome aid to those who are concerned with the teaching or study of the elements of public health. JOHN HALL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON. PH. D.

Professional Training of Sanitarians—A symposium setting forth the British view of adequate hygienic training for medical students, graduates in public health, sanitary inspectors, health visitors. All of interest to American educators.

BUCHAN, G. F., *et al.* The Education of Health Personnel. *J. Roy. San. Inst.*, 51, 2: 73 (Aug.), 1930.

Industrial Nutrition Work—How undernourished employees in one industry are induced to undergo an adequate diet is interestingly told.

COMSTOCK, L. Selling Proper Nutrition to Industrial Workers. *P. Health Nurse*, 22, 8: 406 (Aug.), 1930.

Toxoid or T-A Mixture?—The findings of the National Institute of Health are noteworthy. “(1) In 475 school children diphtheria toxoid gave an immunity response, as measured by the Schick test, of 95 per cent as compared with 64 per cent in 355 children receiving 0.1 L + dose toxin-antitoxin mixture. (2) No local or general reactions were reported in children receiving toxoid; those giving reactions to intracutaneous test injections of diluted toxoid having been removed from the group. (3) Two doses of 1.0 c.c. each, with an interval of 1 month, produced a negative Schick reaction in a high percentage of subjects.”

HARRISON, W. T. The Immunizing Value of Diphtheria Toxin-Antitoxin Mixture and Diphtheria Toxoid. *Pub. Health Rep.*, 45, 33: 1883 (Aug. 15), 1930.

Rickets Prophylaxis—This report illustrates the problems involved in determining the prophylactic dose of viosterol. Larger doses than those for-

merly recommended seem to be in order. No important differences between viosterol and cod liver oil were noted within the limits of this investigation.

Hess, J. H., *et al.* Viosterol (Irradiated Ergosterol). *J. A. M. A.*, 95, 5: 316 (Aug. 2), 1930.

Ergosterol and Cod Liver Oil—The antirachitic potency of the irradiated ergosterols tested varied greatly, and the best had less than 60 times the antirachitic activity of the best cod liver oil.

HOLMES, A. R., and PIGOTT, M. G. The Relative Antirachitic Activity of Cod Liver Oil and Irradiated Ergosterol (Viosterol). *New Eng. J. Med.*, 203, 5: 220 (July 31), 1930.

Childhood Nutrition—“There appears no reason to conclude that a scientifically balanced milk diet, including 1½ pints to 1 quart of milk a day per child, produces greater growth or better health in growing children from 7 to 15 years than a scientifically chosen vegetable diet furnishing a smaller amount of calcium.”

LANE, D. E., and BOSSHARDT, F. H. Nutrition of Children on a Mixed and on a Vegetable Diet. *Am. J. Dis. Child.*, 40, 2: 285 (Aug.), 1930.

Milk-Borne Sore Throat—Another epidemic laid to raw milk, this one an explosive outbreak numbering 187 cases, was caused by dairy workers who apparently infected the milk directly.

LANE, E. A., and ANDERSON, G. W. An Outbreak of Milk-Borne Sore Throat. *New Eng. J. Med.*, 203, 7: 324 (Aug. 14), 1930.

Antirabic Treatment Paralysis—A straightforward account of the risk of paralysis during the course of the

Pasteur treatment with which every health officer should be familiar.

McCoy, G. W. Antirabic Vaccine Paralysis. *Pub. Health Rep.*, 43, 33: 1888 (Aug. 15), 1930.

State Health Administration—This report of a health survey of Iowa is in reality a valuable discussion of health organizations for rural states.

McLAUGHLIN, A. J. A Public Health Survey of Iowa. *Pub. Health Rep.*, 45: 28 (July 11), 1930.

Cross Connections Cautiously—A clear, concise statement of the reasons for, and the dangers of, cross connections and how the danger may be eliminated.

Mowry, C. W. A Practicable Program for the Elimination and Control of Cross Connections. *J. Am. Water Works Assn.*, 22, 8: 1061 (Aug.), 1930.

Preventing Childhood Tuberculosis—Canadian experience in the French scheme of placing children from tuberculous homes, but not yet suffering from the disease, in country foster homes is reported as most successful.

Nadeau, E. The Grancher System, as Applied in the Province of Quebec, for the Protection of Childhood against Tuberculosis. *Canad. Pub. Health J.*, 21, 8: 382 (Aug.), 1930.

Experimental Water Treatment—The city of Ottawa built a trial water treatment plant to determine the conditions and problems involved before the needed municipal filtration system was installed. Such municipal foresight seems unaccountable. The record of the research is most interesting.

Nasmith, G. G. The Trial Filtration Plant, Ottawa, Canada. *J. Am. Water Works Assn.*, 22, 8: 1017 (Aug.), 1930.

The Health of the Worker—Despite improved sanitary conditions and public health service, British industrial experience indicates an increas-

ing duration of illness and recovery from accidents. The reasons for these phenomena are discussed.

Oliver, G. The Health of the Worker Today. *J. State Med.*, 38, 8: 454 (Aug.), 1930.

Symposium on Arthritis—The present status of the problem, diagnosis, vaccine treatment, other biologic products, bacteriologic studies, nutritional factors, and British administrative projects are all included in this fine series of papers which seem to be the last word on this much discussed subject.

Pemberton, R., et al. Symposium on Arthritis. *J. Lab. & Clin. Med.*, 15, 11: 1055 (Aug.), 1930.

Hookworm Eradication Status—The hookworm situation has passed the initial stage of a unique project and has now become a part of the routine of southern clinicians and health officials. Mass treatment without full consent of parents and physicians is highly inadvisable.

Stiles, C. W. Decrease of Hookworm Disease in the United States. *Pub. Health Rep.*, 45, 31: 1763 (Aug. 1), 1930.

Interstate Carriers' Water Supplies—What the U. S. Public Health Service is doing to supervise and certify the drinking water used by interstate carriers makes an effective story of real accomplishment.

Tarbett, R. E. Certifying Water Supplies for Interstate Carrier Use. *J. Am. Water Works Assn.*, 22, 8: 1102 (Aug.), 1930.

Anaphylaxis—Serum reactions are more common with concentrated serum than when unconcentrated diphtheria antitoxin was used. The author believes that the increased sensitivity is not all due to the prophylactic use of toxin-antitoxin mixture.

Toomey, J. A., and August, M. H. Reactions Following Administration of Diphtheria Antitoxin and Toxin-Antitoxin; Results of Desensitization. *J. Prev. Med.*, 4, 4: 281 (July), 1930.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

League of Red Cross Societies—Public attention is being drawn to the problem of blindness. How can human eyesight be saved? It is a matter of common knowledge, but one to which too little thought is given, that there is a belt of countries encircling the world in which the inhabitants are either threatened with blindness or suffering from grave forms of ocular disease; the whole of Northern Africa, including Morocco, Algeria, Tunis and Egypt, the vast expanse of India and the alternately sparsely and densely populated territory of the Chinese Republic are included in this belt. In Western Europe the leading industrial countries, which are now almost immune from certain diseases as a result of the progress made in preventive medicine, have noted a marked increase in the number of accidents resulting in eye injuries. An American ophthalmologist was no doubt thinking of these countries when he declared that "external injury constitutes the most important cause of blindness through the greater part of life."

Among this multitude of unfortunate human beings who have either lost their sight or are threatened with blindness, there are some who could recover their sight if given suitable treatment; there are a far greater number who could be saved from impending blindness. How can this be achieved? This question is answered in the report published by the International Association for the Prevention of Blindness. This document gives figures showing the deplorable amount of blindness in the world and its geographical distribution; in round figures, the blind population of the different countries is given as follows: 500,000 in China, 1,500,000 in India, 76,000 in the United States, 53,000 in Great

Britain, 36,000 in Germany, etc. It has been estimated that 95 per cent of the native population of Egypt suffer from trachoma, while 90 per cent of the school children in Southern Tunis are afflicted with this disease. Up to the present, the vastness of this problem has been a deterrent to initiative. Setting aside these figures, there can be no doubt that the problem of blindness is far from being insoluble; in the majority of cases blindness is caused by avoidable accident or common forms of disease against which we are powerfully protected: smallpox, trachoma, purulent ophthalmia. Too great insistence cannot be laid on the assertion that blindness can be prevented in the great majority of instances.

Hygienic Institute—The 15th report of the Hygienic Institute for the period ending December 31, 1929, is well illustrated and contains much valuable material from an administrative standpoint. It may be recalled that this health organization serves La Salle, Peru and Oglesby. The Tri-City Tuberculosis Society coöperates with the health department in the prevention of tuberculosis and has placed a scale in each of the 23 schools of the communities served, in addition to other provisions.

One nurse is maintained by that organization to work under the direction of the supervisor of nurses at the Institute. The Boards of Education maintain a school nursing program by contributing funds toward the salaries of the school nurses, and the cities also make substantial appropriations for the conduct of the work, in addition to the funds derived from endowment. The Metropolitan Life Insurance Company

has arranged to furnish nursing service to its policyholders through the Institute, which will receive 75 cents per visit.

The year 1929 showed some of the most satisfactory death rates ever recorded; the general death rate being 9.2, corrected for residence 8.3, while infant mortality fell to a rate of 56.3. An interesting table on office and administration activities shows in detail these time-consuming activities which frequently are not recorded by health administrators. Among other items, it is noted that there were 1,102 visitors to the Institute during the year, and 3,336 telephone calls were received, in addition to some 2,000 such calls made.

School physical examinations were made of 2,095 pupils of the 1st, 3d and 5th grades, 1,975 pupils having been found with defects and 2,735 corrections having been made. The report cites the development of certain new educational projects which are worthy of note, including Health Button Contests among school children, and open-window room methods. Disbursements totalled \$38,863 in this district of 30,000 people. The health officer states that while this budget compares favorably with most communities, it is yet not sufficient to meet the full demands of modern public health requirements.

Johannesburg—Johannesburg, with an estimated population for 1929 of 350,500, records a white birth rate of 25.9. The native and colored births registered numbered 1,920, but as the ratio of females to males in these population groups is only 1 to 7, the report points out that it would be misleading to suggest a birth rate. The death rate for all persons from all causes for the past year was 14.9, the rate for white persons being 11.1. Marked improvements are noted in infant mortality rates, due unquestionably to the extension of maternal and infant welfare ac-

tivities and the provision of adequate prenatal facilities in the form of nurses and clinics. The report contains many valuable statistical tables and interesting graphs, accompanied by appropriate descriptive text.

Athens, and Clark County, Georgia—The annual report for the period ending June 2, 1930, is written in an unusually interesting style, and if the size of type were somewhat larger, this report would doubtless be read by a large audience.

During 1929, the negro death rate in the county exceeded the birth rate in the ratio of 182 to 174. Figures are presented to show that among white babies it may be expected that 43 out of 1,000 will not reach their first birthday, as contrasted with 119 for the colored. Considerable progress is noted in the improvement of milk supplies.

New Britain, Conn.—The 1929 report is well printed in type adapted to the soft dull coated paper, easily read. A birth rate of 17.7, a general death rate of 8.3, and an infant mortality rate of 55.7 are recorded. A venereal disease clinic was opened during the year.

An expenditure of 82 cents per capita is noted, but garbage collection accounts for 37 cents of this amount. In this city with a population of 74,240, there were 2,479 laboratory examinations made and 1,127 packages of biologics distributed last year. Wassermann tests are made in the state laboratory. The report concludes with pertinent recommendations by the health officer for future developments, including an isolation hospital, a diphtheria prevention program, a scoring system for dairies, and separation of garbage collection costs from the health budget.

Elizabeth, N. J.—On the basis of a 1929 population of 117,633, a death rate of 9.8 and a birth rate of 17.0 are re-

corded. Infant mortality has dropped from a rate of 165 in 1911 to 64.7 in 1929.

Prenatal cases are visited monthly by the child hygiene nurses when an early engagement of an attendant is urged, together with frequent visits during pregnancy. After the birth of the child, mother and baby are visited weekly for the first month and special stress is laid on maternal nursing. There are 27 licensed midwives who are visited monthly by the supervisor for inspection purposes. It is reported that members of the Union County Midwives Association coöperate well with the health department.

Parochial school health work is carried by the health department, as are dental clinics for school children. Four venereal disease clinics are maintained where 5,518 treatments were given. Home visits for follow up of V. D. cases numbered 643. Approximately 50,000 quarts of milk are sold daily in the city, of which 87½ per cent is pasteurized.

Kent and Queen Anne's Counties, Md.—The frontispiece of the 1929 report of the Kent and Queen Anne's County Health Department is a plan of the proposed child health center building for Queen Anne's County, to be erected some time during the year. The building will supply offices for the health officer and nurse, as well as special clinic rooms, operating room, and wards. A new health center is also being erected in Chestertown, Kent County, which

will house the health officer and nurse and will contain rooms for the various clinics and will be equipped with modern and up-to-date appliances. One feature will be a complete dental equipment. The full-time staff consists of a Deputy State Health Officer, 2 white (1 in each county) and 1 colored nurse, and secretary.

The activities of the Deputy State Health Officer, the colored nurse and the secretary are financed by the State Department of Health. The work of the white nurses is financed by the County Commissioners, the County Public Health Association, and the Maryland Tuberculosis Association. Each county has a part-time county health officer, who is a practising physician, and several part-time clinicians.

Maternal and infant death rates being high, close supervision of midwives is maintained. Each midwife is supplied with a complete obstetrical outfit which is inspected regularly by the county nurse. Classes for midwives are held each year. The school health program in the two counties is based on close coöperation between the Deputy State Health Officers and the Superintendent of Education, and calls for a physical examination of every white and colored child in Kent and Queen Anne's Counties. A chest clinic, a child health conference, and an eye, ear, nose and throat clinic are held monthly in each county. Annual mental and orthopedic clinics are also held in each county.

NEWS FROM THE FIELD

NEW YORK STATE SEWAGE WORKS ASSOCIATION

THE fall meeting of the New York State Sewage Works Association was held at the Onondaga Hotel, Syracuse, N. Y., September 13, 1930.

C. A. Holmquist, President, presided and paid tribute to the memory of Kenneth Allen, founder and first president of the Association.

Following a brief business meeting, two papers were presented, one on "Chlorine Uses at Sewage Plants" by L. H. Enslow of the Chlorine Institute, and the other on "Stream Pollution from the Operator's Standpoint" by Professor E. B. Phelps of Columbia University.

TEXAS PUBLIC HEALTH ASSOCIATION

THE Texas Association of Sanitarians, at its eighth annual short school, August 26-28, changed its name to the Texas Public Health Association. Dr. H. K. Read, supervisor of hygienics in the public schools of Houston, was reelected president. Other officers chosen were: vice presidents Jack Wyatt, Amarillo, Dr. T. A. Ward, Beaumont, W. N. Dashiell, Fort Worth, and Celia Moore, Austin; and E. G. Eggert, sanitary engineer for the state department of health, was reappointed secretary.

J. C. Anderson, M.D., state health officer of Texas, was honored by the Association as "a man who has accomplished more for the health of Texas in his unselfish way than, perhaps, any other man." Dr. Anderson was presented with a billfold as a token of appreciation of his services and accomplishments, which were outlined briefly in a presentation speech by Dr. Read.

Houston was selected for the 1931 meeting city. Dallas, Austin, Waco, and other cities had extended invitations to the short school. Among the resolutions adopted was one placing the association in favor of simplification of all plumbing codes.

The organization also went on record for encouragement of proper methods in collecting and disposing of garbage and recommended a permanent program of rat-proofing by incorporating a section of this phase of public health in all building codes.

By resolution the sanitarians endorsed and pledged support to the standard milk ordinance program.

MICHIGAN CONFERENCE

ON September 11 and 12 the Upper Peninsula Conference on Public Health and Tuberculosis was held in Marquette under the auspices of the Michigan Public Health Association and the Michigan Tuberculosis Association.

THE BURKE FOUNDATION

A BUILDING for recreational therapy and remedial social activities will shortly be opened in connection with the Convalescent Institute of the Burke Foundation at White Plains, N. Y. This will release more bed space for women patients.

CHILD STUDY ASSOCIATION

A THREE-DAY conference with Round Table Discussions will be held October 20-22 at the Hotel Pennsylvania, New York, N. Y., under the auspices of the Child Study Association of America.

The Conference will be opened with

a dinner, October 20, the subject of which will be "The Family and Fulfillment of Personality." Dr. Frankwood E. Williams will be Chairman. Speakers will be Dr. Hornell Hart, Dr. Beatrice Hinkle, Dr. H. E. Barnard, and Dr. Eduard C. Lindeman.

BI-CO-LI

THE Order of the Bi-Co-Li will meet at the Texas Hotel, Fort Worth, Tex., during the A. P. H. A. Convention.

MENTAL HYGIENE INSTITUTE

THE Philadelphia Hospital, Philadelphia, Pa., announces the opening of its Institute for Mental Hygiene. The Institute is planned for patients who will meet the physicians more than half-way in recognizing that they need help—for fatigue, worries, fears, maladjustments, difficulties in getting on with other people or at their work. The services are for both out-patients and resident patients.

The Institute will try to furnish an actual cost-of-care service designed to give people of moderate means every essential of good treatment including privacy and choice of physician, but with no element of charity.

ROCKY MOUNTAIN SPOTTED FEVER

DR. R. R. Spencer, U. S. Public Health Service, was awarded the Gold Medal by the American Medical Association in annual session at Detroit in June, 1930, for original work in the preparation of a vaccine against Rocky Mountain spotted fever.

A 5-year record of practical prevention of Rocky Mountain spotted fever achieved by Dr. Spencer was the basis for the award of the medal.

Until 1924 laboratory workers knew no special prophylactic inoculation, and of 16 exposed 6 contracted the disease and all died. Since 1924 there have been 59 laboratory workers all of whom

have received prophylactic inoculation and among these there have been 7 cases all of whom recovered, except 1 who received only one of the two requisite prophylactic doses.

FELLOWSHIP IN CHEMICAL RESEARCH

THE Secretary of the Treasury has recently accepted a gift of \$100,000 offered by the Chemical Foundation, Inc., through its president, Francis P. Garvan, under the provisions of the Act of May 26, 1930, which authorizes the government to accept donations and to create a system of fellowships, etc., in the National Institute of Health. The condition is made that the income from this fund be used for one or more fellowships in basic chemical research in matters pertaining to public health, the details of which are left to the Surgeon General and his Advisory Committee.

FLIGHT DOCTORS' COURSE

A POSTGRADUATE class in aviation medicine and surgery, believed to be the first of its kind, will be offered next fall by the University of California. The new course is to deal with all phases of a flight surgeon's work.

Colonel Edward L. Munson, 9th Army Corps surgeon, and Colonel W. A. Powell, professor of medico-military science, will direct the course for the university's medical school.

AMERICAN EDITORS' AND AUTHORS' ASSOCIATION

THE American Editors' and Authors' Association, in convention at Detroit, Mich., June 24, 1930, adopted a resolution recommending the creation of a Portfolio of Public Health in the Cabinet, and that a copy of the resolution be forwarded to the Secretary of State, Washington, D. C., to the secretaries of all national and state medical organizations, and to all members of the said association.

SMALLPOX PRACTICALLY EXTINGUISHED IN BULGARIA AND HUNGARY

SMALLPOX in Bulgaria and Hungary where vaccination is compulsory is apparently almost extinct. Its rarity is evident from the fact that Dr. A. Petrillo, of the State Hygienic Institute of Budapest, and Dr. Ilia G. Minoff, a public health official of Bulgaria, who were visiting health organizations in New York State, said that they had never had an opportunity of seeing a case of smallpox in their native countries.

Dr. Petrillo asked if there had been any recent cases in the state. He was informed at the time that reports of smallpox were being received from a community in the southern section and that if he left immediately he would be able to see patients in various clinical stages. In the course of a week he visited, with the district state health officer, a large percentage of the 39 cases which occurred in one community during this outbreak. None of these cases had ever been vaccinated.

GEORGE ROBERT WHITE FUND

THE Sixth Health Unit, established from the income of the George Robert White Fund, was dedicated and presented to the City of Boston on September 15.

PERSONALS

DR. J. T. AINSLIE WALKER, of London, died suddenly on July 27. Dr. Walker is best known in this country for his pioneer work in the standardization of disinfectants. In collaboration with Dr. Samuel Rideal, he gave us the first really satisfactory method for determining the comparative value of disinfectants, their

method being known as the Rideal-Walker Test. After the recent war, Dr. Walker formed the Ainslie Walker Laboratories, Ltd., for the purpose of carrying on research and chemical manufacturing, principally in the disinfectant field. In England he was considered an outstanding authority on disinfectants.

DR. W. CARSON RYAN, JR., Professor of Education at Swarthmore College, has been appointed Director of Education in the Indian Service, Department of the Interior.

MRS. A. F. FANGER, of Hialeah, Fla., was elected Historian of the National Congress of Parents and Teachers.

KENNETH ALLEN, Fellow A. P. H. A., sanitary engineer for the Board of Estimate and Apportionment of New York City since 1916 and who was to have been retired because of ill health, died September 9, in his home at White Plains. He was born in New Bedford, Mass., seventy-three years ago and was graduated from Rensselaer Polytechnic Institute in 1879.

KATHERINE Z. W. WHIPPLE has become secretary of the health education service of the New York Tuberculosis and Health Association, succeeding Iago Galdston, M.D., who is now director of the medical information bureau of the New York Academy of Medicine.

CHARLES O'HAGAN LAUGHING, M.D., Member of the A. P. H. A., State Health Officer of North Carolina, died August 26. **H. A. TAYLOR**, M.D., was named Acting State Health Officer until a successor is appointed.

DR. JOEL A. SPERRY, formerly of New Haven, Conn., is now Professor of Bacteriology at Pennsylvania State College, State College, Pa.

The Incidence of "Jake" Paralysis in Oklahoma*

DAVID T. BOWDEN, M. D., F. A. P. H. A., L. A. TURLEY, Ph. D.,
AND H. A. SHOEMAKER

Director, Laboratories and Rural Sanitation, State Health Department, Oklahoma City, Okla.; Professor of Pathology, University of Oklahoma; and Assistant Professor of Pharmacology and Biochemistry, University of Oklahoma, Oklahoma City, Okla.

ON February 28, Dr. Earl T. McBride of the McBride Reconstruction Hospital, Oklahoma City, called to ask if we would check his laboratory in the examination of the spinal fluid from two patients who had come to his hospital showing a peculiar paralysis. He stated that there was some resemblance to both anterior poliomyelitis and Landry's disease, but that there were additional features in both cases, characteristic of neither. In both the spinal fluids were negative.

About the same time Dr. W. H. Miles, Oklahoma City Health Officer, and Dr. E. Goldfain, an associate of Dr. McBride, investigated 60 cases which came to the attention of the City Health Department. It was found that in every instance the condition affected those going in or frequenting the same section of town; that this section was the location of certain drug stores which were suspected of violating prohibition laws; and it was significant that a number of their employees, and one or two proprietors were afflicted. Careful investigation revealed that the only etiological factor common to all of these cases was a history of habitual indulgence in "Jake."

To Drs. Miles and Goldfain credit should be given for the first indictment against fluid extract of ginger as the causative agent. A number of the druggists selling this product had been visited by federal agents and samples of the fluid extract picked up for analysis. Ord-

* Read before the Epidemiology Section of the American Public Health Association at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

nary methods showed them to be standard in every respect, but more careful analysis revealed them to be low in ginger extractives. After the appearance of these cases samples were again obtained and analyzed for heavy metals. It was at first announced that the paralysis was due to lead poisoning. The mistake made was in the finding of a so-called "passive" sulphate of iron which precipitated out after sulphuric acid digestion and returned to solution quite slowly.

The authors felt quite certain that the clinical symptoms were not due to lead, and I believe the case histories given here will bear us out. Preliminary chemical work was started, details of which will be given later.

In the meantime numerous facts of interest began to come to light. Cases were reported from other sections of the state. On April 1 cards were sent to about 2,500 physicians in the 77 counties of the state. On April 23 approximately 40 per cent of these had been returned and showed 536 cases in 39 counties. Because of the tendency to be ashamed of the affliction it is safe to assume that this number represents only about one-third of the cases and that there are therefore between 1,500 and 2,000 in the state. Reports and inquiries began to come in from all sections of the country, notably, Alabama, Mississippi, Georgia, Kentucky, Tennessee, South Carolina, North Carolina, Louisiana and Ohio. Different theories were developed as to the cause, all of which broke down under investigation.

Three instances suffice to show how each additional report strengthened our belief in the fundamental truth of our own theory. From Tulane came the report that a physician who was treating several such cases had become paralyzed himself. He denied ever having used "Jake" and the inference was naturally drawn that we were dealing with some type of low grade infection. The cat escaped from the bag when the patients stated that the doctor had purchased his ginger from the same source as themselves. Again—

The connection of fluid extract of ginger with these cases is being generally definitely established, though there have been some instances where the use of ginger extract has been denied. One such case was the superintendent of a mill in Georgia who was affected with the paralysis, which the doctor diagnosed as the result of ginger drinking, though the patient denied it. The doctor, however, confirmed his diagnosis by means of a ruse, telling the patient's wife that he was writing out a prescription which might be of benefit, but if he had been drinking ginger extract not to give it to him as it might produce fatal results. The patient then announced he would not use the prescription.¹

Finally, there is the instance of the girl whose mother gave her half

an ounce of fluid extract of ginger to relieve the pains of dysmenorrhea and who later developed the paralysis.

After becoming convinced of the fact that ginger extract was the causative agent we began to cast about for the ingredients at fault. Numerous statements appeared, all of which were considered carefully before being discarded. Among them were the following: that lead or some other of the heavy metals were to blame; that the paralysis was due to water passing through deposits of bauxite; to a fungus growth on the ginger; to another root closely resembling ginger but containing a toxic alkaloid; to use of ginger which had been redistilled, thus rendering the product toxic.

The application of cold reasoning ruled out most of the above, and chemical analysis eliminated the rest. The reasoning followed was based on the fact that the condition made its appearance nearly simultaneously in widely separated parts of the country, that cases originated only during a very brief period of time (no new cases are being reported); that in all the centuries during which ginger in various forms had been used as a condiment, seasoning, flavoring material, confection, or drug, no record of a similar outbreak could be found.

All of the above points led to the assumption that some new adulterant was being used in the preparation. That there was reason for suspecting this is supported by the fact that standard preparations of ginger contain such a quantity of ginger extractives that extreme dilutions are necessary before the fluid becomes potable, and such dilutions reduce the alcoholic content until the desired "kick" cannot be obtained. The first adulterant suspected was iso-propyl alcohol. This was found in varying quantities in several samples, but the findings of others² convinced us that this was in no way concerned unless there was a chemical combination with some of the ginger extractives. Animals were therefore fed fluid extracts made of African and Jamaica ginger, using as a menstruum ethyl alcohol denatured with 1 per cent iso-propyl. Dogs fed 1 oz. of the above preparations showed no symptoms after from 6 to 10 weeks.

During the course of these experiments, the first autopsies on cases of ginger paralysis were held.

Case I. Male, white, age 68, laborer. Had been heavy consumer of alcohol all his life. No history of venereal disease. No Wassermann. Developed a well marked case of "Jake" paralysis, following debauch. Came into hospital with cough and lung symptoms premonitory of pneumonia, and general malaise. Râles in bases of both lungs. Blood pressure not obtainable because of arteriosclerosis. On the third day he developed stertorous breathing and other symptoms of brain pathology. He died about 48 hours later.

Autopsy showed generalized arteriosclerosis. Some pulmonitis but no definite

pneumonia. Liver somewhat retracted, slightly nodular, darkly mottled. Kidneys not remarkable. Brain described as water-logged. Spinal cord and sciatic nerve, no gross pathology. Cause of death, cerebral edema.

Microscopic sections of the organs showed nothing remarkable. First examination of the material from the nervous system was made by Dr. H. G. Jeter, who reported cellular exudate in some of the fibers of the cauda equina as the only lesion found, and on this basis made a diagnosis of perineuritis. Sections were run by the routine histological methods.

In this laboratory the material was run through special neurological methods using sudan IV-hematoxylin, toluidin blue, and osmic acid stains.

Sudan IV-Hematoxylin. Lower lumbar cord. (1) Brownish red granules packed in marginal area in all nerve cells of the anterior horns. Similar brownish granules in some cells of dorsal horns. (2) Karyolysis, either breaking up of nucleolus—condensation of karyosomes, or complete lysis of karyotin material with disappearance of nucleolus. (3) Migration of the nucleus in many cells. Edema and lymphocytic exudate around the neural canal, desquamation of neural canal epithelium.

Toluidin blue stain shows presence of tigroid bodies—but with frayed margins—in all cells containing a nucleus in good condition, except in regions of the cell occupied by granular material described above. This type of pathological condition of nerve cells was also found in the upper thoracic, lower cervical cord, medulla including the inferior olive, nuclei of the floor of the fourth ventricle at this level, and the dentate nucleus.

Osmic acid-Mueller stain of material from the same regions revealed black granules in all places where Sudan IV had shown brownish red granules.

Marchi stain of the sciatic nerve showed (a) in cross sections some fibers in every fascicle which stained black; (b) in longitudinal section, some fibers were all black, others showed black masses at the nodes of Ranvier, or scattered along in the internodal spaces.

The exudation around the neural canal was found at all levels of the cord examined, but not in the region of the fourth ventricle.

Case II. Male, white, age about 70. Always used alcohol. No history of venereal disease. No Wassermann. "Jake" paralysis, or locomotor ataxia. Came into hospital in semi-comatose condition. Died after short stay. Diagnosed possible uremia.

Autopsy revealed aneurism of ascending aorta, atheromatous aorta, and arteriosclerosis. Other organs not remarkable. Complete central nervous system removed together with sciatic, anterior tibial, part of brachial plexus, and radial nerves. No gross pathology evident except probable swelling of anterior tibial nerve. The special staining methods used in Case I showed identical pathology of nerve cells and fibers with that case.

It occurred to us that if the pathology is due to "Jake," and it has, as in Case I, reached the vital centers, the symptoms and death could be due to the changes described above. The symptoms would be those involving the failure of the vital centers, and death from "Jake" is possible.

Since the microscopic findings in the above cases seemed to us to

be unique, and—with only 2 cases autopsied—characteristic, we set about to determine, if possible, the causative agent. On April 25 one of the authors (D. T. B.) visited L. T. Hoyt, Chemist in Charge Federal Prohibition Laboratory at New Orleans, La., where he learned that some samples seized had shown the presence of a phenol compound which had not been positively identified but was thought to be tricresyl-phosphate. Analysis up to this time, by the methods of Fuller and Authenreith & Warren, had failed to disclose anything unusual. This may have been due to the fact that the samples analyzed by us had actually not contained the adulterant. Taking advantage of the findings of Mr. Hoyt, an attempt was made to isolate and identify the phenolic substance suspected. No tests could be found in the literature available, and after some experimentation the following procedure, modified from Fuller, was adopted:

Sixty c.c. of the fluid extract of ginger was placed in a small distilling flask, connected with a condenser and placed in a water bath. The alcohol was distilled and collected for examination. The residue was diluted with water, transferred to a separatory funnel and extracted with ether. The ether solution was then extracted with a 5 per cent alkali solution, washed with distilled water, extracted with dilute sulphuric acid, again thoroughly washed with distilled water, filtered, and the ether evaporated on the water bath.

After the beaker and contents had cooled, the residue from the ether solution was thoroughly extracted with petroleum ether. Upon evaporation of the petroleum ether, a rather viscid, slightly yellow residue was obtained. The distillate from this residue when warmed with alkali and distilled after acidification with sulphuric acid gave strong positive tests with Millon's reagent, bromine water, and the formaldehyde and sulphuric acid reagent. The precipitate was amorphous with the bromine water and did not give the pink color that is obtained with phenol. In other words, the indications are that it was a cresol rather than a phenol.

The residue in the flask still contained a large amount of undissolved material which was washed with concentrated sulphuric and nitric acids until a colorless solution was obtained and tested for phosphate with ammonium molybdate. A very positive test was obtained. From the manner of the extraction and the tests, it was assumed that the substance was tricresyl-phosphate. Quantitative analysis showed the substance to be present in a strength of about 3 per cent.

Having convinced ourselves of the identity of the adulterant chemically, experiments were made to substantiate our belief by pharmacological and pathological methods. Ten chickens and four dogs have been used.

Technical tricresyl-phosphate was secured and administered to young, full grown chickens and dogs. The dosage for chickens was 5 c.c. administered orally with a catheter. In about a week there were symptoms of unsteadiness in the use of the legs of the chickens, which became more pronounced in 24 hours; at this time another dose

was given. The 9th day from the initial dose, foot drop and difficulty in using legs were very marked in all chickens; 2 days later cyanosis of the comb and respiratory embarrassment were present, and about the 11th day, the chickens died. Since the behavior of the chickens and the symptoms which developed were identical with those which had received dosages of Jamaica ginger that had produced paralysis in human beings (see Figures I and II), we felt assured that the deleterious substance that had caused the epidemic of paralysis in humans was tricresyl-phosphate.

FIGURE I

Chicken 1. 5 c.c. Tricresyl-phosphate, 6/5/30—Repeated 6/13/30, Photographed 6/16/30—Died 6/16/30, P.M.

FIGURE II

Chicken 2. 15 c.c. Deco Ginger, 6/5/30; 10 c.c. Deco Ginger, 6/13/30, Photographed 6/16/30, Killed for Pathological Study 6/21/30.

Misfortune overtook the dogs before we had finished our studies. One was taken by some students by mistake and used in an experiment in another department. A second, which at the end of the 8th week had developed marked loss of use of hind legs and feet, also respiratory embarrassment including almost complete loss of voice, was likewise destroyed prematurely. The third escaped just after it had begun to show symptoms; and the fourth, though showing early signs of poisoning, has not advanced sufficiently at this time to warrant pathological examination. However, our experiments showed that while paralysis of dogs by the use of Jamaica ginger containing small percentages of tricresyl-phosphate was attained with great difficulty; nevertheless, they could be paralyzed by the drug alone, although the onset is slow. The dosage was 10 c.c., administered by mouth at 3-day intervals. Two doses were given to each animal.

Further to prove the question in point, it seemed advisable to try the effect of Jamaica ginger containing tricresyl-phosphate. For this purpose a sample of Jamaica ginger was secured which contained no cresyl or phosphate and was known to be of U. S. P. Standard. Four groups of two each of chickens were used. To one Jamaica ginger not containing tricresyl-phosphate was given; to the other three Jamaica

ginger containing various percentages of tricresyl-phosphate. The results are shown in Table I.

DISCUSSION OF TABLE

The results of these experiments are interesting for a number of reasons. The experiments showed: (1) Jamaica ginger not containing tricresyl-phosphate produced no paralysis or paralytic symptoms, and aside from the initial intoxication following the administration had no effect on the well-being of chickens; (2) Jamaica ginger containing as little as 1.5 per cent of tricresyl-phosphate would cause paralysis and even death of chickens; (3) in proportions greater than 3 per cent, death would occur in a few days—in our experiments, 14 days.

Another interesting point was the difference in the resistance of the different chickens to the ultimate effect so far as time was concerned. It will be noticed that chicken No. 6 received 1.5 per cent of tricresyl-phosphate and died in about 19 days, while chicken No. 8, which was

TABLE I

Chicken No.	6/2/30	6/24/30	6/30/30	7/3/30	7/9/30	7/10/30	7/12/30	7/14/30	Ultimate Fate
3	Gin. 1	Gin. 1	Well	Well	Well	Well	Well	Well	Dead 7/20*
4	Gin. 1	Gin. 1	Well	Well	Well	Well	Well	Well	Killed 8/15†
5	Gin. 2	Gin. 2	Leg weakness	Leg & foot weakness marked	Paralysis severe	Feet weakness	Feet useless, swelling of eyes	Condition same, respiratory trouble	Killed 8/15†
6	Gin. 2	Gin. 2	Leg weakness	Leg & foot weakness marked	Paralysis, respiratory trouble	Dead			
7	Gin. 3	Gin. 3	Leg weakness	Leg & foot weakness marked	Paralysis, respiratory trouble	Condition worse	Dead		
8	Gin. 3	Gin. 3	Leg weakness	Leg & foot weakness marked	Paralysis, respiratory trouble	Feet useless, respiratory trouble same	Condition same	Condition same	Dead 8/14
	6/21/30	6/24/30	6/27/30	6/30/30	7/5/30				
9	Gin. 4	Gin. 4	Leg weakness	Paralysis marked	Dead				
10	Gin. 4	Gin. 4	Leg weakness	Paralysis marked	Dead				

Different samples of ginger are marked: 1, no tricresyl-phosphate; 2, 1.5 per cent of tricresyl-phosphate; 3, about 3 per cent; and 4, about 4 per cent tricresyl-phosphate. The doses were 5 c.c. of each mixture with 15 c.c. of water administered by mouth.

* The cause of death of chicken No. 3 on July 20 was not determined. It was apparently all right at 5 P.M., July 19. It had not at any time shown any effect of the ginger, and at autopsy none of the pathology found in those showing the effects of ginger.

† Chickens Nos. 4 and 5—One well and one paralyzed. Since they had shown no change for over 3 weeks, it was decided that it was more valuable to make microscopic examinations of them than to keep them living for a longer period.

given 3 per cent, lived 53 days. The time of the appearance of initial symptoms was practically the same for all concentrations used, in this series being about 9 days. Another similarity was that, regardless of the duration of life following the onset of symptoms, all of the chickens developed respiratory difficulties; all died in coma; and all developed edema of the orbital region with watering of the eyes. The paralysis in all cases was very similar to that found in humans in "Jake" paralysis—toe drop, inability to use the feet, and while the legs could be moved they could not be used for ambulation. So far as we were able to discern the chickens' wings were not affected.

We were somewhat disappointed in the microscopic examination of the central nervous system, in that we did not find the fatty degeneration which was present in the human cases. We did, however, find karyolysis, karyorhexis, and degeneration of the nerve cells as shown by the difficulty or inability to stain them by any method. We may say that the typical pathological lesions so far as the central nervous system is concerned in cases of intoxication resulting from tricresyl-phosphate are karyolysis, karyorhexis, and degeneration of the cell bodies, the exact type depending on the animal affected.

A very interesting series of experiments on rabbits, dogs and calves, by Smith,³ arriving at similar conclusions, differs from our work in that we were able to produce symptoms in dogs and were able to compare human and animal pathology.

Sanitary Features of Irrigation*

JANE H. RIDER, C. E., F. A. P. H. A.

Director, Arizona State Laboratory, Tucson, Ariz.

IN the desert more heed is given to water than is necessary in a country with a plentiful rainfall. It is the very basis of existence; with an ample supply the country prospers; without it the land remains barren. To supplement the shortcomings of nature in failing to provide a method to catch and retain the scant rainfall allotted to the Southwest, dams and reservoirs have been constructed to impound the surface runoff of storms so that the water may be conserved for use during dry seasons. The largest of these projects have been for irrigation and have had a direct effect upon the ground water levels of the irrigated valleys, building up a secondary underground storage of water.

The climatic condition normal to the arid Southwest may be somewhat better understood at this time when so much of the country has been suffering from drought. The normal annual precipitation for Arizona is 13.61",¹ varying from 3.10" at Yuma with an elevation of 150 ft. to 32.42" at Crown King with an elevation of 6,000 ft. The low humidity prevailing increases evaporation to such an extent that it is from 4 to 29 times the amount of rainfall. Such a condition makes "dry-farming" an impossibility.

When such a situation exists all water is valuable, regardless of its sanitary quality—the great concern is to utilize every drop. To do this the relatively pure impounded surface runoff is used for irrigation. This water percolates down through the soil, is pumped to the surface, and again irrigates crops. Raw sewage and the effluent from sewage treatment plants are also used for irrigation. The application of water to the land for growing crops is the same in each case; however, when sewage is employed more careful farm management is necessary, and the crops that can be grown are limited by custom and public health regulations.

The main canals of an irrigation system should be considered, for sanitary purposes, as streams with controlled flow. Taking the place

* Read before the Public Health Engineering Section of the American Public Health Association, at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 28, 1930.

of small rivers that flow through territory with more abundant rainfall, they are used by camps of agricultural workers for drinking water, washing clothes, swimming, watering live stock, and many other domestic purposes. The water in canals is usually of fairly good quality at the main diversion dam, but as it flows through the miles of cultivated area pollution increases until at the end of the system it has none of the clear, sparkling qualities so desirable in potable supplies. Samples taken at the head of one of the main canals of a large project² had a count on agar at 37° C. of 150 bacteria per c.c. and *B. coli* group in one of five 10 c.c. portions. After flowing 16 miles, largely through farm land, there was an average count of 1,800 and 100 *B. coli* per c.c. At this point the entire flow of a river was diverted into the canal. The river water had an average total count of 2,000 per c.c. and 10 *B. coli* per c.c. Some 24 miles farther down the canal the average count was 2,600 and 1,000 *B. coli* per c.c. The dissolved oxygen of the canal water ranged from 6.90 to 11.55 p.p.m. and the 5-day oxygen demand from 0.2 to 6.35 p.p.m.

There was no evidence along the banks of the canal of any quantity of pollution entering the stream. Trash and refuse are sometimes thrown in the canal, the bodies of small animals are occasionally seen floating along, and the water which is clear at the diversion dam becomes muddy and contains floating grass and weeds.

Maintaining a canal system in a sanitary condition throughout its entire length would be a problem of magnitude. The canal mentioned above, one of the four main canals on the project, has a normal flow varying from 40 to 242 sec. ft.; after rains, when no water is needed for irrigation, the bed may be nearly dry. It is approximately 40 miles long, and there are many additional miles of laterals and ditches. Chlorine introduced at the canal heading would be dissipated long before the farm area was reached and would not take care of incidental pollution. Streams receiving sufficient raw or partially treated sewage to deplete the oxygen and materially increase the *B. coli* content should be purified to some extent before being used for general irrigation. It would be much simpler to treat and sterilize the sewage, though it is sometimes a problem to convince town councils of the wisdom of this policy.

It is difficult, if not impossible, to control the sanitation of the camps of unskilled laborers who are brought into an irrigated area. These workers, poor and ignorant, with no background of cleanly traditions, live in shacks under the trees along the canal banks. Their methods of waste disposal are primitive; if not carefully watched they will place privies on the inner bank of the canal, which also serves as

their water supply, bath tub, and laundry. Despite these conditions, remarkably few cases of water-borne diseases have been attributed to the use of canal water. In a few instances people swimming in the canals have contracted typhoid fever. In tracing the source of these infections we have on 2 occasions found a case among the Mexicans in a nearby camp. These patients were sent to a hospital and no further cases occurred in those districts. The flies that breed about these camps we feel are much more of a menace to health.

A few years ago a newspaper syndicated article blamed a typhoid outbreak in Chicago on lettuce grown in the irrigated districts of the Southwest. The health authorities claimed oysters were the causative agent, but unfortunately the accusation of the unscientific writer had much greater circulation than the health report, and it appeared that the lettuce growers would be heavily penalized unless this statement could be proved false.

We examined lettuce from 16 fields in different parts of the Salt River Valley and 2 in the Eloy district and found no evidence of *B. typhosus* or allied organisms. Many heads of lettuce were cultured and, while our technic was hastily devised, we felt if there had been any general contamination some indication of it would have been found.

In the irrigation districts with which I am familiar the *B. coli* in canal water originates from animal or agricultural sources. Human pollution is very slight, unless towns empty sewage into a stream that is later diverted for irrigation; even in this case dilution may furnish a factor of safety. A. L. Dopmeyer, Assistant Sanitary Engineer, U. S. Public Health Service, and the writer made a sanitary survey of an irrigation system alleged to be furnishing grossly polluted water. Our findings did not indicate any contamination sufficient to endanger the health of consumers of vegetables grown on land irrigated from these canals.

Mosquitoes may be a resultant evil of irrigation. In Arizona the topography and nature of the soil have largely prevented conditions favorable for their propagation. The main breeding places are in the weeds and grasses growing along the banks of drainage canals with low velocity or in water that is allowed to overflow the ditches and stand in ponds outside the fields. This latter is somewhat controlled by the Water Users' Associations that impose penalties for wasting water.

Irrigation as a means of land disposal of sewage has a most favorable field of operation in the Southwest. The scant annual rainfall, low relative humidity, and economic value of water present conditions for its success. With few streams having an average flow sufficient to

furnish dilution water, broad irrigation seems the logical method for final disposal of sewage. The management of a disposal farm is similar to that of any other sewage plant, and the results are directly dependent upon the ability of the employees.

There has been a tendency in recent years to disparage this method of disposal, but in the arid sections of the country its value is being more appreciated each year. California and the City of Los Angeles are studying land filtration and the recovery of water. It does seem futile in a country where water is so badly needed to waste the moisture content of sewage by allowing it to flow aimlessly down a dry arroya or into the ocean.

It is doubtful if irrigation with raw sewage will ever be an unqualified success; the nature of the solids and the amount of nondigestible cellulose tend to clog the soil and limit the type of crops that can be grown. Bar screens and preliminary sedimentation are necessary to give a sufficiently clear effluent for use without causing excessive odors or clogging the soil. More complete treatment serves to minimize these difficulties. With proper farm management the effluent from septic tanks can be used on crops without causing complaint.

Phoenix, Ariz., has a contract with a rancher to dispose of the 7,320,000 gal. per day effluent from the septic tanks. These tanks are old and overloaded; the effluent has a high oxygen demand, a pervasive hydrogen sulphide content, and large *B. coli* count; with all these faults it irrigates 300 acres of land on which are raised hay and grain sufficient to feed 1,000 head of stock a year. The rancher claims he can produce better crops and pasture nearly double the amount of stock that is possible on farms irrigated with canal water. The soil conditions are particularly favorable for disposal, being virgin river bottom land with a loose loam surface. At times it takes the entire flow for 26 hours to irrigate 10 acres.

This is the silver lining—the cloud also has a very dark side. The maximum water needed for irrigation is 980,000 gal. per acre per year, or for 300 acres 294 million gal., whereas the city delivers 2½ billion gal. of effluent to the farm. There is a large loss from evaporation, but the sun and climate have not prevented sufficient overflow to ruin the recreational features of the river for some miles below. The city is now having a more complete treatment plant designed so that the excess water can be sold to one of the irrigation districts.

The Tucson disposal farm, owned and operated by the city, has 355 acres under cultivation, with more being prepared for crops. Coarse bar screens and mechanical clarifiers treat the sewage before it is applied to land; the sludge is pumped to a four-compartment di-

gestion tank and when dried is used as fertilizer. The farm is operated by a skilled agriculturist who, by careful management, has been able to use a maximum of $7\frac{1}{2}$ acre ft. without spoiling the crops by over-irrigation. This excessive quantity will be reduced as more land is cleared and levelled. About 2,400,000 gal. of clarified sewage are delivered to the ditch each day.

The maximum penetration noted after heavy application of sewage was 24 in. The farm lies along the Santa Cruz River; occasionally irrigation water reaches the dry channel through gopher holes or when it overflows from adjacent fields. A cased well 75 ft. deep near the heading of the ditch shows a consistently good quality of water.

The hydrogen sulphide in the effluent as it enters the ditch is from 1.5 to 2.0 p.p.m.; one-quarter of a mile farther on, at the corner of a highway, there is still sufficient gas to cause some complaints from motorists. As the district about the farm builds up it is felt that it will be necessary to give the sewage some further treatment so the effluent will be more stable when delivered.

Crops of corn, barley, milo maize, higuera, and cotton are grown; sheep are used to keep the Johnson grass out of the ditches; and experiments are now being made with hog feeding. The income from the farm pays all of the operating costs of the plant and most of the fixed charges. This year it may show a slight profit. Certainly this is a safer and saner method of disposing of plant effluent than allowing the partially treated liquid to flow down the dry channel of a river, relying on infrequent floods to carry away the deposited solids.

Any project whether irrigated with impounded surface runoff, drainage water pumped onto the land, or clarified sewage, offers many problems in sanitation. Waste disposal and mosquito control are much the same as in any rural districts, and there is the usual question of obtaining a satisfactory water supply for household purposes. When no suitable ground water is available at reasonable depths, the supply must be taken from the canals. Various types of home-made filters and sedimentation in jars are used to clarify the water, but no efficient simple means has been devised to purify it. True, it might be boiled for 20 minutes, but in a country with a mean maximum summer temperature of 100° F., cooling boiled water is no easy matter for a farm laborer's wife. The type of worker who lives along the canal banks is bewildered by even simple directions for sterilizing a bucket of water with some chlorine preparation.

The Control of Thermophilic Bacteria in Pasteurizing Plants*

M. W. YALE AND ROBERT S. BREED, PH. D., F. A. P. H. A.

Department of Dairy Industry, Iowa State College, Ames, Ia.; and New York State Agricultural Experiment Station, Geneva, N. Y.

THE control of thermophilic bacteria in pasteurizing plants is a problem receiving much attention. Lack of information on control under practical operating conditions led to a series of studies by the authors which were carried out in 1928 and 1929 in coöperation with the manufacturers of pasteurizing equipment, the departments of health, and the milk companies concerned.

The five market milk plants studied were large ones with pasteurizing runs of 5 to 7 hours, located at Buffalo and Syracuse, N. Y.; and Pittsburgh, Pa. Two of these used Burrell long flow holders, two Electropure flash, and one Creamery Package coil vat pasteurizers.

The general plan followed was first to take a series of samples at various stages during the pasteurizing run to gain a general idea of the situation. Counts were made by the direct microscopic method, and by the agar plate method, incubating the plates at 37° C. and 62.8° C. Comparison of plate counts at the two temperatures showed that many thermophiles failed to develop at 37° C. The direct microscopic method proved valuable in detecting an increase in thermophiles, as those encountered were large rod shaped spore-forming bacteria of types not commonly found in the raw supply. A few samples were examined with the methylene blue reductase test, using 62.8° C. as the incubation temperature and a layer of paraffin oil as a seal. This proved satisfactory and a microscopic examination of the milk after reduction revealed apparently pure cultures of rod shaped bacteria.

After a general idea of the situation had been obtained, an attempt was made to reduce the number of thermophiles by controlling the factors favoring their development.

Out of the mass of data secured in studies that occupied about five months, the results of certain instructive analyses are given.

* A preliminary summary of this paper is given in the *J. Bact.*, 19: 46-47, 1930. Other studies in the same series are published as *Bulletins* of the New York Agricultural Experiment Station, and may be secured on application to that Station.

TABLE I

THE RAPID DEVELOPMENT OF THERMOPHILES AT PLANT A, AS SHOWN BY THE INCREASE IN THE DIRECT MICROSCOPIC COUNT IN THE MILK LEAVING THE LONG FLOW HOLDERS—

* The direct microscopic counts of individual bacteria for the first 2 hours cannot be considered accurate, because of the possibility of confusion with rod shaped bacteria of other types. Returned pasteurized milk was sometimes mixed with the raw supply, which explains the variations encountered at the start. Where spaces are blank, no samples were taken.

Examination of the raw supply at the five plants showed few thermophiles, usually less than 500 per c.c. as determined by an agar plate count at 62.8° C. Several exceptions were noted, indicating that unusual conditions may produce a high thermophile count in the raw supply. Return of unsterile moist cans to the producers proved to be one of these conditions. No method of completely eliminating thermophiles from the raw supply was found.

At one of the plants using long flow holders and at that using coil vat pasteurizers, the small number of thermophiles in the raw supply proved sufficient to inoculate the pasteurizing equipment so that, with careless operation, several millions of thermophiles per c.c. ordinarily appeared in the pasteurized milk toward the end of the run. In the two cities concerned, the situation was only partially appreciated by the officials in charge of milk inspection, as the number of colonies developing on standard agar plates from bottled milk picked up at random varied from less than 10,000 per c.c. to less than 100,000 per c.c. Many of the colonies obtained were of the pin-point type and the records of the two companies, as would naturally be expected from the fact that the samples examined were selected at random over a long period, were very irregular and inconsistent.

Table I shows the development of millions of thermophiles per c.c. during a 5- to 6-hour pasteurizing run at Plant A where two Burrell long flow holders were in use. The factors responsible for this rapid

development were found to be (1) presence of thermophiles in the raw supply, (2) prolonged holding of milk at pasteurization temperature, (3) repasteurization, (4) cooking of milk solids on to the walls of heaters, (5) presence of dead ends, and (6) the development of thermophiles within the holder. Each of these factors was studied individually.*

That faulty plant operations were of greater importance than the type of equipment and presence of thermophiles in the raw supply is shown in Table II, which gives the results of studies made at Plant B. Plant B used a Burrell long flow holder similar to that at Plant A, but none of the faulty operations found in Plant A were practised. This limited the development of thermophiles to two factors: (1) presence of thermophiles in the raw supply, and (2) development within the holder itself. Table II shows that only 60,000 to 600,000 thermophiles developed per c.c. in a 4-hour run, as disclosed by direct microscopic examination, in contrast to several millions per c.c. at Plant A during a run of the same length.

TABLE II

THE COMPARATIVELY SLOW DEVELOPMENT OF THERMOPHILES AT PLANT B, AS SHOWN BY THE DIRECT MICROSCOPIC COUNT ON MILK LEAVING A LONG FLOW HOLDER—
CAREFUL OPERATING CONDITIONS

Date	Start to First Hour	First to Second Hour	Second to Third Hour	Third to Fourth Hour
Sept. 17, 1928	<10,000	<10,000	60,000	60,000
Sept. 19, 1928	<10,000	<10,000	<10,000	600,000

Repasteurization of milk returned from routes was practised at one plant using Burrell long flow holders and at one using Electropure pasteurizers. This was mixed with the raw supply previous to repasteurization. At the plant using the long flow holders, the discontinuance of repasteurization reduced the number of thermophiles but did not correct the trouble until other faulty operations were corrected.

Conditions were not favorable for the development of thermophiles with the Electropure process, on account of the high temperature employed (73° C.) and the installation and uniform operation of equipment. Table III gives the results of studies at two plants, C and D, using Electropure pasteurizers. These were operated in the same way except that repasteurization was practised at C but not at D. Table III shows that repasteurization was responsible for an increased development of thermophiles at Plant C, although the numbers were

* A detailed study is given in *Technical Bulletin No. 156* of the New York Agricultural Experiment Station, Geneva, N. Y.

not high as compared with those found in the other plants studied. Where no repasteurization was practised the increase was negligible. The small numbers of bacteria present made a direct microscopic count impossible and necessitated the use of agar plates incubated at 62.8° C.

Prolonged holding at temperatures above 37° C. was a factor in the development of thermophiles. At one of the plants using long flow holders, this was brought about by stopping the milk pump to wait for milk at the receiving platform, and by having a greater pasteurizing than bottling capacity which caused shut-downs. At the plant using the coil vats, there was poor management and some of the batches were held from 1½ to 2 hours at the pasteurizing temperature. Table IV shows that samples of this milk, taken from the same vat at intervals, gave a decreasing 37° C. plate count due to the destruction of the less heat resistant bacteria, and an increasing direct microscopic count due to the development of thermophiles. It shows in a striking way that special methods are necessary for the detection of thermophiles, as the 37° C. plate count alone would not have revealed their presence.

The rôle that filter cloths played in the development of thermophiles depended entirely on the temperature at which the milk was filtered and the length of time that the filters were in operation. Contamination from filter cloths was an important factor at the plant using the coil vats. This plant filtered the hot milk following pasteurization, the same filter cloth being used throughout the run of approximately 5 hours. Three or four stops of 10 to 20 minutes were ordi-

IN THE SAME VAT OF MILK AS A RESULT OF PROLONGED HOLDING AT
PASTEURIZATION TEMPERATURE

Date	Holding Time	37° C. Plate Count	Direct Count of Thermophiles
Aug. 19, 1929	20 minutes	70,000	30,000
	60 "	16,000	75,000
	90 "	7,000	900,000
	110 "	5,000	1,800,000

narily made, due principally to a greater pasteurizing than bottling capacity, but could have been reduced by better management. The filter was connected in such a way that it remained filled with hot milk during any period in which the machinery was stopped. Table V shows that these stops were instrumental in building up a thermophilic flora in the filter cloth so that contamination persisted after the milk that was allowed to stand in the filter during the idle period had been pumped out.

The findings were also confirmed by direct microscopic examination of milk and sediment scraped from the filter cloth at the end of the run, which showed enormous numbers of thermophilic bacteria. The increase was evidently due to development of thermophiles in the meshes of the filter cloth, resulting in an ever increasing contamination of the pasteurized milk. Replacing the cloths with fresh ones at 2-hour intervals, combined with draining the hot milk from the filter during stops, reduced the number but did not entirely eliminate them.

Filtration previous to pasteurization and at a lower temperature with changes of cloths at frequent intervals may be recommended as a means of controlling thermophiles. In fact, certain sanitary codes, like that of New York State, require that "pasteurized milk shall not be strained or filtered except through a metal strainer so arranged as to be sterilized with the bottling machine."

Examination of the coating of milk solids formed on the tubes of heaters and regenerative heater coolers revealed this at times to be a

TABLE V

THE CONTAMINATION OF PASTEURIZED MILK WITH THERMOPHILES FROM THE FILTER CLOTH
WHERE PASTEURIZED MILK WAS FILTERED FOLLOWING A 30-MINUTE STOP

Date	Description	37° C. Plate Count	Direct Count of Thermophiles
Aug. 20, 1929	Pasteurized milk entering filter following a 30-minute stop after milk standing in the line had been pumped out	12,000	4,500,000
	Same milk leaving filter	59,000	9,000,000

veritable culture of thermophiles. It was here that the first noticeable increase in the number of thermophiles took place within the long flow holders and Electropure pasteurizers. The extent of the coating and the temperature were determining factors. The extent of the coating depended upon the kind of equipment and the method of operation. At one of the plants using long flow holders, the temperature of the circulating water in the internal tube heater was 10 to 15° higher than that of the milk. As a result, there was a large amount of milk solids cooked onto the tubes. Failure to keep the tubes bright and clean, faulty automatic temperature control and undersized heaters were factors responsible for an abnormal amount of cooking.

The development of thermophiles within the pasteurizer proved to be an important element. In the long flow holders, the inner walls of the milk tubes became seeded with thermophiles early in the run and the milk in passing through washed off ever increasing numbers. With the coil pasteurizers, a film of milk remained on the sides and bottom of the vats after emptying which contained a large number of thermophiles and served to inoculate each succeeding batch of milk. Last milk drained from vats always contained an increased number of thermophiles.

DISCUSSION

Control of the development of thermophiles in a pasteurizing plant must be varied with the type of equipment. With the positive hold type, it is possible to rinse the vats between runs while, with the long flow holder, this is not feasible unless a second complete set of equipment is provided for use during the washing period. With the Electropure equipment, growth in the heating chamber is not important because the temperature of 73° C. is too high to favor the development of thermophiles.

Variations in equipment and methods of operation caused each plant to present an individual control problem. Faulty plant operations proved to be more important factors in developing thermophiles than the type of equipment. At well operated plants, faulty conditions were brought under control regardless of the type of equipment.

SUMMARY

1. Studies on the development of thermophilic bacteria, at five large pasteurizing plants with runs of 5 to 6 hours' duration, are presented. Two of these plants used Burrell long flow holders, two Electropure flash and one Creamery Package coil vat pasteurizers.

2. An examination of the raw supply of these plants showed few thermophiles present—usually an agar plate count at 62.8° C. of less than 500 per c.c.

3. Data secured with careful and careless operation of Burrell long flow holders are presented which show that factors involving faulty plant operations, such as (1) prolonged holding of milk at pasteurization temperature, (2) repasteurization, and (3) cooking of milk solids on the walls of heaters, are the most important elements in the development of thermophiles.

4. Studies of Electropure pasteurizers at two large plants showed that conditions were not favorable for the development of thermophiles, chiefly because of the high temperatures employed and the uniform flow during operation. Where repasteurization of returned milk was practised, an increased number of thermophiles was found, although smaller than with any of the other types of equipment.

5. At the plant using the coil vats, prolonged holding at pasteurization temperature gave a decreasing 37° C. standard plate count and an increasing direct microscopic count of thermophiles.

6. Filter cloths were an important source of contamination where hot pasteurized milk was passed through a cloth used continuously for 5 hours, and where milk was allowed to stand hot in the filter during stops.

7. Each plant presented an individual control problem because of variations in equipment and methods of operation. Faulty plant operations proved to be more important factors in the development of thermophilic bacteria than the type of pasteurizing equipment.

NOTE: The author wishes to acknowledge his indebtedness to Dr. R. S. Breed of the New York Agricultural Experiment Station, under whose direction the work has been carried out and who has offered comments and criticisms on this paper.

Training

THE student takes something from a bottle, places it in a test tube, pours on it most any kind of acid and it turns a beautiful green. This experiment carries the label science; it is checked and the next one taken up with a certain superficial seriousness which covers over the knowledge on the part of the student that he is fooling, but getting a credit. This does not breed character. The magic word, Science, is, however, used, and something is done mechanically because the book said do it. No thought nor reason is expected or used. A certain number of carefully guarded Carnegie units are attached to it and the student goes ahead in a mechanical fashion for some more of these units so that he may enter a pre-medical course at college. He has been made to think of gain and not accomplishment, of advancement, rushed, forced advancement, and not of reason, judgment, poise, and beauty. The goal is becoming clearer. Two, three or more years of this and then medicine. There are those who can survive it, who can develop characteristics suitable for medicine in spite of it, and there are many who have not been subjected to a type of training which gives to them that which they did not have.—William DeB. MacNider, M.D., *South. M. J.*, Dec., 1929.

Sickness Records in School Hygiene

JEAN DOWNES

Division of Research, Milbank Memorial Fund, New York, N. Y.

THE adequacy of the school medical examination, even in its more highly developed form, as a means of keeping tab on the school child's health, is properly being called into question. The principal ground for skepticism is the obvious fact that the periodic health examination takes into account only a few conditions at intervals of 2 or 3 years; it cannot promptly bring to light any conditions as they arise in the interim. Furthermore, the health examination does not and cannot, unless it is made far more searching than it is now, bring to light other impairments and defects, and it cannot conform to a fundamental postulate for accurate diagnosis, namely, the opportunity for continuous observation.

It may as well be taken for granted that practical considerations preclude a method of continuous examination and observation of millions of children that a competent diagnostician would regard as satisfactory for an individual child. What the school health administrator wants is improvement in the prevailing procedure that will result in the prompter discovery and correction or treatment of important conditions that now are not brought to light at all or with too much delay. Evidences of this desire are to be seen in efforts to improve the medical examination itself and to supplement it with more frequent inspections by teachers and nurses, and by referring conditions thus discovered for special medical examination.

Another supplementary method, which has been discussed by Collins,¹ and in a limited degree proposed by the American Public Health Association's Committee on Record Forms,² and employed in an even more limited extent in a few localities, is a current record of absence from school on account of sickness. The possible uses of sickness records as a supplementary method of keeping in closer touch with the health of school children have been stated succinctly by Collins, as follows:

The school sickness record would serve the double purpose of a continuous record of the health of the child and a criterion for referring children for special examination. Any child who suffers frequent attacks of illness which entail absence

from school may well be referred for examination, even though the condition is only headache, for it will enable the physician to discover in their early and preventable stages physical impairments which otherwise might be serious.

It is the purpose of this paper to report briefly the results of an experiment which had for its purpose the discovery by (1) medical examination, and (2) sickness records, of conditions that might need correction or treatment.

The experiment was conducted in the public schools of Olean, a city of about 23,000 inhabitants, in Cattaraugus County, N. Y., where for several years an experiment in rural health administration has been carried on with financial support and technical assistance from the Milbank Memorial Fund. In 1926 Edgar Sydenstricker, Director of the Division of Research of the Milbank Memorial Fund, suggested to Dr. C. A. Greenleaf, director of the Cattaraugus County School Health Service, that a record be made by the teachers as to the condition or disease causing all pupils' absences for which sickness was ordinarily given as the reason. The cause of illness was obtained from the written explanation of the child's absence signed by a parent or some responsible member of the family. In many cases the cause of absence was checked by the school nurse either by telephone or a visit to the child's home.*

The present report is based on the experience of two school years in one graded school. During these 2 years 475 pupils were enrolled, but only those who were in attendance 1 or 2 full school years were included in the record considered here.† For convenience in summarizing the results for 2 school years, a child attending (i.e., enrolled) for 2 years is counted as 2 (i.e., 2 "years of observation") and the statistics are stated in terms of 825 children enrolled for 1 school year; throughout this paper, therefore, the term "child" means a school child observed for 1 school year although the great majority of individuals were observed for 2 years. All of the children were in the age group 5-14 years, were fairly equally distributed as to sex,

* It was found that conditions and diseases could be entered usually by means of a simple code in the regular school registers or roll books.

The code used was as follows:

c—cold
m—measles
d—diphtheria
t—tonsillitis
u—mumps

w—whooping cough
i—indigestion and headache
f—scarlet fever
h—teeth
p—chicken pox

s—continued illness
r—weather
a—cause other than illness
x—unknown

Under "continued illness" was included surgical cases, fractures, tuberculosis, heart trouble, etc. The cause of "continued illness" usually was stated.

† A few pupils entering during the first month or leaving the last month of a school year were included.

and were nearly all white native born, and of native born parents.* The school was considered as representative of the various types of home environment such as are ordinarily found in a city of this size in the western part of New York.

Of these 475 pupils, 329 were given one "complete" physical examination; 103 were given two such examinations; about 230 were examined especially for nose and throat conditions by the school physician; and 3 tuberculosis contacts had special clinic examinations during the 2-year period. The results of an examination are related to the sickness record for the year in which the examination was made. About 30 children had no regular physical examination. All of the routine physical examinations were made by the school physician except for teeth, which were done by a dental hygienist, and for Snellen tests which were made by teachers and nurse. The examinations may be regarded as typical of the better grade of school physical examinations.

It was thus possible, for a large majority of the children, to utilize the records both of physical examinations and of sickness.† The morbidity experience and the findings of the physical examinations in the 2 school years are summarized in Tables I and II.

In general, the relative importance of the principal causes of sickness is similar to that reported by Collins³ and by Sydenstricker⁴ for children of similar ages, and thus may be considered fairly typical. The interesting and, from the point of view of this discussion, extremely significant indication afforded by this record is the fact that children were absent from school on the average nearly 4 times a school year for a total of nearly 8 school days for causes which, with few exceptions, obviously are not taken into account at all, or at least not directly by the physical examination. In mitigation of this apparent condition it may be said that the great majority of these causes are merely temporary ailments—such as "colds" and "upset stomachs"; yet it cannot be denied that as much responsibility rests upon school health authorities to see that actual cases of measles, whooping cough, tonsillitis, earache, toothache, and the like are followed up to

* The age distributions for both and either sex were as follows:

	5	6	7	8	9	10	11	12	13	14	Total
Both sexes	84	77	72	96	97	114	103	97	50	35	825
Boys	50	41	44	39	51	62	48	38	24	14	411
Girls	34	36	28	57	46	52	55	59	26	21	414

† For this purpose the various records for each child during the 2 school years 1926-1927 and 1927-1928 were transcribed on to a single sheet which eventually contained the record of previous communicable disease incidence, immunizations, scholastic failures, record of sickness, and the results of whatever physical examinations were made during the period. The records of children who were transferred from and to other schools were completed, and the children who stopped school were followed up to ascertain the cause of discontinuance.

* Includes all respiratory diseases except pneumonia and tonsillitis and sore throat.

† Includes headaches.

‡ Includes rheumatic fever, appendicitis operation, sore eyes, boils, nervous prostration, heart, undefined abscess and illness from scarlet fever inoculation.

the same extent as ear, eye, or tooth defects found upon relatively infrequent examinations. In fact, the question properly may be raised as to whether or not a child who is subject to frequent respiratory or digestive disorders, even though they may be mild, should be regarded with as much concern as if he or she had a "3x" defect of some sort.* Table III shows the frequency of absences per school year on account of "colds" and "indigestion and headache."

Clearly, a record of sickness reveals cases that constitute legitimate problems for the school health service. Certain of these are not shown at all or, at best, indirectly by the routine physical examination; such as cases of whooping cough, measles, and other infectious diseases, frequent colds, headaches, and digestive disorders. On the other hand, it is equally clear that certain defects and impairments may not be revealed at all by a sickness record for the simple reason that they

* Another method would be to consider cases of a given length of absence for such causes as "colds," as needing follow-up, but the frequency of their occurrence would seem a satisfactory criterion.

* It is realized, of course, that a more specific record as to digestive attacks, and as to headaches, would be desirable.

do not manifest themselves in actual sickness although they may eventually cause ill health. The two methods are complementary, even for those conditions which are included in both.

If the fairly common assumption were true, that a medical examination, as a method of revealing hidden defects and impairments, is an adequate means of appraising the health of the individual, one should expect a fairly consistent and high correlation between the existence of defects or impairments and the incidence of actual sickness during a period of 2 years in a group of school children. This was not found to be the case in the experience recorded. In order to ascertain how far the assumption was justified, the children in this school were divided into two categories: (1) those found upon physical examination to be normal or to have a slight abnormality (1x), and (2) those having any defective condition serious enough to warrant notification of the parents that the condition needs attention (2x and 3x), and the general illness rates for these two classes were computed. Table IV and Figure I give the comparison by age groups. The illness rate varies according to age, as may be expected, but evidence that it is higher among children with gross defects than among those who are free from them is by no means definite. It may be argued that this lack of association is due to inadequate examinations; possibly this is in a measure true, but our observation was that the physical examinations in this school, which were made by the director of the school health service, were done with more care than is ordinarily found in routine work of this kind.

----- This comparison may be carried a step further by comparing the prevalence of *specific* defects among 221 children suffering less than the average number of sicknesses and among 176 children who were sick frequently (5 attacks or more per year) as is done in Table V.

Now the striking fact shown by this comparison is not that the defect rates were generally somewhat higher in the "sickly" group, but that relatively a small proportion of 176 children who were actually sick 5 or more times during a school year were discovered to have *any*

serious defects upon physical examination. In other words, the findings of the physical examination, even when considered from the point of view of specific and serious conditions, are a poor indication of the extent to which the child is actually sick.

Again, we may consider certain defects which may be reflected directly in sickness of the same specific nature, such as diseased tonsils and tonsillitis, and carious teeth and toothache. By including chil-

dren who had special nose and throat examinations in addition to the regular physical examination, we had a total of 767 children observed for 1 year. Relating the sickness record to the same school year in which the examination was made, the children were classified into two groups: those with "normal" or "1x" tonsils and those with "2x" or "3x" tonsils. In the latter group there were 163 children, all of whom presumably were referred for correction. But of the remaining 604 children with "normal" or "1x" tonsils, 59 actually suffered one or more attacks of tonsillitis or sore throat. Six of them had attacks in each of the 2 school years. A considerable number of these, if not all, properly should be considered as needing examination and probably attention. Similarly, 177 children were found upon examination to have teeth needing attention, but of the 413 children whose teeth were in satisfactory condition when the examination was made, 73 actually suffered one or more toothaches that resulted in absence from school.

Summarizing the results of the experiment, it appears true that the proposal of the American Public Health Association Committee on Record Forms to utilize sickness records as a means of discovering conditions in school children that may need treatment or correction, is a sound one in principle. A current record of sickness undoubtedly reveals many conditions which the medical examination does not bring to light. Obviously, if the sickness record is made specific enough as to cause, along the lines suggested by Collins, the information thus gained is more effective than merely a record of the number of days lost on account of illness without reference to more than a few general causes. How practicable will be the actual reference of children to physicians and clinics as the result of recording and reporting illnesses of specific kinds, is a question which must be determined by further experimentation. It is planned to make such an experiment in the near future and, if possible, to measure its results in the terms of treatments, corrections and improvement in health of the children as compared with results obtained in schools where ordinary medical examinations and school inspection alone are in operation.

A Peep into West Indian Medical History

J. A. OGILVIE

Porus, Jamaica, B. W. I.

NOW that American citizens are taking a keener interest than ever before in the West Indies, both from the standpoints of health and commerce, a peep into the sad records and deplorable conditions of past and bygone days will, I am sure, convince readers how completely modern sanitary science has changed the medical history of these charming and picturesque islands.

Up to quite recent times, the white Northerner upon visiting the West Indies was in danger of being attacked by remittent or intermittent fever, dysentery, or yellow fever, and frequently did not survive his arrival by more than a few weeks, while the mortality among the white troops was simply staggering.

Formerly five years were sufficient for the disappearance of a white regiment of 1,000 men, and sometimes in a single year a regiment would lose 300 men.

The sanitary conditions were awful; pools of stagnant water were everywhere; and refuse matter, exposed to heat and air, accumulated and decayed in the yards, streets and barracks; in short, sanitary arrangements of any kind were nonexistent, public health duties being entirely relegated to the John Crows (vultures), and these repulsive birds, harbingers of death, could daily be seen by the scores, actively and energetically engaged in dismembering the putrefying bodies of dead animals, unmolested and undisturbed by passers-by.

Is it any wonder that less than a hundred years ago service in the West Indies was looked upon as almost certain death? Yellow fever was the chief destroying angel, with intemperance as the principal contributory cause, for many of the European soldiers took to drink at the wretched life and hopeless outlook, and deaths from delirium tremens were frequent. The salt meat they were obliged to eat caused a raging thirst which the rum bottle only aggravated. The sad story is summed up by one medical writer in the following words: "Our troops in the West Indies are killed by drinking new raw rum; and so are the lower order of mechanics and white people on the plantations."

In Jamaica in the years 1817 to 1836, the mean mortality was 121.3; the mean of the 4 healthiest years gave 67, and of the 4 unhealthiest years, 259 per 1,000 of strength. Between 1837 and 1855, the mortality had declined one-half. In 1864, the mortality was much below the home standard. In 1867, it ran up nearly to the old number from the prevalence of yellow fever, which appeared again at Newcastle and caused a greater loss than it had done in 1860. (No epidemic of yellow fever has occurred in Jamaica since 1897.)

In Trinidad and Barbados, the mortality was somewhat lower than in Jamaica, but the graves of whole battalions are still to be seen in their cemeteries, and bear silent testimony to the horrors of the past.

Toussaint L'Ouverture was doubtless an exceptional man, and rightly made use of circumstances to achieve his ends, but if history is true, Hayti owes her independence more to the malignant form of yellow fever which decimated the French and English armies than to any military genius which he exhibited. The white troops sent to Hayti from Jamaica between 1795 and 1798 were troops condemned to death, it being related that one whole regiment from colonel to drummer boy was exterminated by yellow fever, not a single man surviving. An entire French army under General LeClerc was in its turn almost annihilated by this dread malady in 1802 and 1803.

Today the mortality of the West Indies compares favorably with that of most American cities, and the white man from northern latitudes; be he American, Canadian, or European, enjoys as good health in the perpetual summer of these sunny islands as he does under his own temperate skies, provided he cultivates regular habits and avoids intemperance.

This transformation has been brought about by a more accurate knowledge of the causes of disease, and still more gratifying results will follow when the technical means of prevention are more efficiently applied.

The change which has taken place during the 20th century in the health conditions of these sun-kissed isles of the West vividly emphasizes the truth of the Latin maxim *Homini nihil utilius homine*, for this remarkable achievement has only been rendered possible by the self-sacrifice, devotion and martyrdom of members of the medical profession who concentrated their efforts on research and experimental work to the end that the human family might enjoy freedom from pestilence and disease.

A Bacteriological Study of Grade A Pasteurized Milk

CECIL BROOKS

*2nd Lieut., M. A. C., U. S. Army, Second Corps Area Laboratory,
New York, N. Y.*

THE Second Corps Area Laboratory, as does every other Corps Area or Department Laboratory of the U. S. Army, examines samples of milk sent to it through the mail by medical officers of some large and many small stations within its Area. The Second Corps Area Laboratory is situated at 39 Whitehall Street, New York, N. Y. It serves the First as well as the Second Corps Area; hence the region from which it receives samples takes in all of New England, New York, New Jersey and Delaware. It is evident that bacteriological examination of milk in the Second Corps Area Laboratory must perforce be done by the direct microscopic method. The method of preparing samples for shipment to the laboratory is set forth in Army Regulations 40-310, Section XII, pars. 31 and 32, which are quoted verbatim.

Section XII

SPECIMENS OF MILK

	Paragraph
General provisions	31
Preparation of milk for shipment	32

31. General provisions—The information to be gained by the examination of specimens of milk shipped to laboratories is so limited that such examinations will always be conducted locally wherever laboratory facilities are available. For specimens forwarded by mail, resort must be had to the direct-count method of determining the bacteria present rather than to the colony count. The direct-count method indicates the actual number of bacteria present and bears no relationship to the actual number of living organisms present at the time the specimen is collected. This is especially true in the case of milk that has been pasteurized. The direct-count method, therefore, is an index of past pollution rather than of the number of living organisms present, and its correct interpretation is based largely on a knowledge of the character of the milk at time of collection, whether raw or pasteurized, and on the sanitary condition of the dairy from which it came. All dairy-men supplying stations or commands will be required to furnish the surgeon of the command a quart bottle of milk, on request, at least once each month for examination. The specimen to be analyzed will be selected at random from the delivery wagon. If the specimen is not to be examined locally, the bottle will immediately

be placed on ice pending its preparation for shipment. The specimen will be shipped on the day of collection.

32. Preparation of milk for shipment—A special container, capacity 120 c.c., in mailing case, is supplied for shipment of milk specimens. The following procedure will be carried out in preparing the specimens for shipment: The quart of milk will be poured 25 times between sterile containers in order that the milk and cream may be thoroughly mixed and that clumps of bacteria may be broken up. After thorough mixing, add 1 c.c. of commercial formalin to the quart of milk and agitate thoroughly to insure inhibition of further growth of bacteria. Then fill the sterile container. It is essential that the bottle containing the specimen be filled flush to the lower end of the stopper to prevent churning of the specimen with formation of butter while in transit. Secure the stopper by binding the muslin cover in place with the copper wire. Test for leakage. Label and prepare forms as directed in paragraph 4 and note on the label the name of the dairy and the word "formalinized." Pack securely in the mailing case with absorbent cotton.

Apparently no adequate standards of direct microscopic counts of pasteurized milk exist. In fact, the application of the direct microscopic method of counting bacteria to pasteurized milk is not commonly advised. Certainly the counts arrived at by direct microscopy of pasteurized milk represent not the number of living bacteria but the number of bacteria both living and dead. To quote *Standard Methods of Milk Analysis*, A. P. H. A., 5th Ed., p. 26:

Where there is reason to expect the presence of dead as well as living organisms, as for example in pasteurized milk, it is improper to regard microscopic counts as counts of living bacteria. Valuable information may, however, be obtained by making comparative plate and microscopic counts from samples of pasteurized milk.

With this in mind and with a view of establishing standards for our own use which would enable us to interpret our routine counts, a study was made of the pasteurized Grade A milk of two of the largest distributors in New York City. Quart bottles of milk were taken from the regular morning deliveries; 10 deliveries being made over a period of 4 weeks.

Examination of the milk was begun about 2 hours after delivery. Each quart was divided into 5 parts. The first part, about 160 c.c., was examined immediately, as received. Four lots of 200 c.c. each were preserved with formalin at that time and were examined on the following day.

Examinations made of milk untreated with formalin were: methylene blue reduction test; direct-count of bacteria and leucocytes; stroke cultures of 1:100 dilution on the surface of blood agar plates; and standard agar pour plates, using two dilutions, 1:100 and 1:10,000. With two exceptions, the examinations were the same for the formalinized specimens. Agar pour plate cultures of the

1 : 10,000 dilution were omitted in the case of the formalinized specimens, as were also the blood plate cultures.

Because of the routine use of formalin for preserving specimens of milk received for examination by the Second Corps Area Laboratory, the influence of formalin upon the reductase tests and microscopic counts of bacteria and leucocytes in this study were of considerable interest. Four quantities of formalin were used in order to find the quantity which would least interfere in these examinations and still inhibit the growth of bacteria in the milk. The four quantities of formalin used were 0.2, 0.5, 1.0 and 2.0 c.c., each in 200 c.c. of milk, thus giving percentage solutions of 0.1, 0.25, 0.5 and 1.0, respectively.

Formalinized milk was held at room temperature for about 24 hours before examination. This insured the milk practically the same treatment as if it had been shipped from a distant station.

METHYLENE BLUE REDUCTION TESTS

All methylene blue reduction tests were made in duplicate, using 10 c.c. quantities of milk. The reduction time recorded is the average for the two tests. The difference in time required for reduction in the two tests was never appreciable. The time required for reduction in all the tests is shown in Table I.

TABLE I

REDUCTION TIME FOR ALL TESTS

Specimen	Dairy	1	2	3	4	5	6	7	8	9	10
Unformalinized	No. 1	0	X	X	X	X	X	X	X	X	X
	No. 2	0	X	X	X	X	X	X	X	X	X

	No. 2	0	0	0	0	0	0	0	0		

0—not reduced overnight

Figures—reduction in hours

X—reduction overnight

Soon after beginning this study, it was evident that the larger quantities of formalin used, 0.5 and 1 per cent, were sufficient to prevent reduction of methylene blue. Accordingly, after the 8th delivery of milk, examinations of specimens containing those quantities of formalin were discontinued.

The smaller quantities of formalin affected reduction in the opposite manner from the larger amounts. Reduction was hastened. The reduction time of the 0.25 per cent formalin-treated milk more

nearly agreed with that of the untreated milk than did the reduction time of any of the other specimens.

The figures available are too meager to do more than indicate that the optimum amount of formalin to use lies somewhere around 0.25 per cent. No ratio between reduction time of formalinized and unformalinized milk may be established. It is certain that the reductase test is of no value with pasteurized milk containing as much as 0.5 per cent formalin and it is of doubtful value when the milk contains as little as 0.1 per cent formalin. When reduction with milk containing 0.25 per cent formalin is not complete within $5\frac{1}{2}$ hours, the milk probably contains few bacteria, but reduction in a short time does not necessarily denote a large number of bacteria. The significance of the reductase test is not indicated by this study.

CULTURES

Blood plate cultures of 1 : 100 dilutions of unformalinized milk were made by surface stroking. Hemolytic streptococci never were found in these cultures.

Standard agar pour plate cultures of 1 : 100 and 1 : 10,000 dilutions of unformalinized milk and 1 : 100 dilution of each specimen of formalinized milk were made. The average standard plate counts in unformalinized milk were: No. 1, 5,800; No. 2, 9,800. This gives a general average count of 7,900, which is well within the limit of 30,000 allowed by the *New York State Sanitary Code*. The figures from which this general average count is derived are given in Table II.

TABLE II
ESTIMATED BACTERIAL COUNTS PER C.C. OF MILK BASED ON COLONY COUNTS

Examination	No. 1	No. 2	
1	1,400	12,000	
2	300	9,700	
3	12,000	2,800	
4	1,500	3,000	
5	6,500	8,900	
6	(Excluded)*	17,000	
7	800	9,600	
8	11,000	13,000	
9	17,000	7,700	51,900
10	1,400	14,000	97,100
Totals	9) 51,900	10) 97,100	19) 149,000
Averages	5,766	9,710	7,842
	or 5,800	or 9,800	or 7,900

* An unusual specimen. The milk contained 50,000 large, coarse bacilli per c.c. This was interpreted as either pasteurizer or bottle contamination.

In the cultures of formalinized milk, the smallest quantity of formalin proved sufficient to inhibit growth. None of the cultures contained more than three colonies.

MICROSCOPIC EXAMINATIONS

The microscopic examinations were quite complete. Both leucocytes and bacteria were counted. Mononuclear and polynuclear leucocytes were counted separately, as were the coccoid and bacillary forms of bacteria. The cocci and bacilli were counted both as individuals and as clumps or chains.

The technic employed was a slight modification of the Breed Method as described in *Standard Methods of Milk Analysis*, 5th Ed. The spreads were stained with Wright's stain instead of methylene blue. All counts were made as accurately as possible. With the exception of 3 counts in which 40 fields were used, counts were based on examination of 20 fields. Two spreads were made for each count, 10 or 20 fields being examined on each spread.

While the majority were fairly uniform and near the average, some of the microscopic counts varied greatly from the average. Averages of all microscopic counts are shown in Table III.

TABLE III
AVERAGES OF ALL MICROSCOPIC COUNTS

Nature of Specimens	Individual Bacteria	Groups of Bacteria	Leucocytes
Unformalinized	1,700,000	480,000	1,400,000
0.1 % formalin	1,400,000	420,000	1,200,000
0.25 % formalin	1,500,000	480,000	1,100,000
0.5 % formalin	1,500,000	370,000	1,000,000
1 % formalin	1,500,000	420,000	840,000
General average	1,520,000	434,000	1,108,000

It may be seen in Table III that formalin makes no considerable difference in the count of bacteria, but very definitely affects the leucocyte counts, the larger amounts of formalin lowering the leucocyte counts.

DISCUSSION

In all, 87 specimens are considered in this study. Each of the 20 quarts of milk was divided into 5 parts, 4 of which parts were formalinized. Eight specimens were not examined. One quart (five specimens) of milk was arbitrarily excluded from consideration because of its unusual nature. This milk contained about three times as many bacteria in culture and more than twelve times as many microscopically as any other milk from either of the dairies. It is

thought that the bacteria, principally bacilli, may have been due to pasteurizer contamination; another suggestion is bottle contamination. This milk was pasteurized in Orange Co., N. Y. All the other milk was pasteurized in New York City.

The data presented show that Grade A pasteurized milk may contain millions of dead bacteria per c.c. Milk with an average plate count of 7,900 has been found to contain an average of 434,000 (roughly 440,000) groups of bacteria per c.c., about 1 to 55. Using the same ratio with a plate count of 30,000, which is allowed by the *New York State Sanitary Code*, it is found that an average of 1,650,000 groups of bacteria per c.c. may be present.

It cannot, of course, be claimed that 1,650,000 groups of bacteria per c.c. is the maximum number to be allowed for Grade A pasteurized milk. It is probably fair and reasonable to adopt the rule, at least tentatively, that pasteurized milk should not be classed below Grade A unless it contains more than 2,000,000 groups of bacteria per c.c.

In comparing direct-counts of pasteurized milk with plate counts, a high ratio must be used; certainly nothing like the ratio of 4 to 1 used for raw milk may be considered. The ratio evolved through this study, 55 to 1, has held fairly well in most of the examinations made.

An average of three and one-half times as many individual bacteria as groups of bacteria has been found in direct-counts. There seems to be no good reason to continue to count individual bacteria in future routine examinations. Groups are much easier to count and the counts of clumps and chains mean just as much as the laboriously made counts of individual organisms, at least in pasteurized milk.

Little has been gained by making separate counts of coccoid and bacillary forms of bacteria or of polynuclear and mononuclear leucocytes. No relation between the number of cocci or bacilli and the number of leucocytes was found. Three polynuclear to two mononuclear leucocytes were found quite regularly, but the cocci and bacilli were distributed very irregularly.

SUMMARY

Grade A pasteurized milk, part of which was formalinized, was used for reductase tests, direct-counts of bacteria and leucocytes, blood agar plate cultures and standard agar plate cultures in an attempt to establish standards to use in interpreting results of routine bacteriological examinations of formalinized, pasteurized milk at the Second Corps Area Laboratory. Eighty-seven specimens were used in this study.

Each sample of milk was examined as delivered and again after preservation with 0.1, 0.25, 0.5 and 1.0 per cent formalin. Even in the smallest amount, the formalin stopped growth of bacteria. It did not change counts of bacteria in the

microscopic examinations, but it did lower the leucocyte counts. The two larger amounts of formalin prevented reduction of methylene blue, while the smallest amount hastened reduction. A percentage of 0.25 formalin appeared to better advantage than the other quantities. The significance of the reductase test has not been shown.

The average standard plate count was 7,900.

Surprisingly high direct-counts were obtained. Roughly, averages were: 1,500,000 individual bacteria; 440,000 groups of bacteria; 1,000,000 leucocytes.

The ratio between standard plate counts and microscopic counts of groups of bacteria in Grade A pasteurized milk was found to be 1 to 55.

Pasteurized milk should not be classed below Grade A unless it contains more than 2,000,000 groups of bacteria per c.c.

Three and one-half times as many individual bacteria as groups of bacteria were found in direct-counts.

Counts of individual bacteria, counts of cocci and bacilli separately and counts of mononuclear and polynuclear leucocytes separately were not worth the effort required.

CONCLUSIONS

1. In pasteurized milk, a ratio of 55 to 1 may be used to compare direct-counts of bacteria with standard plate counts.

2. Grade A pasteurized milk may contain fully 2,000,000 groups of bacteria per c.c. in direct microscopic counts.

NOTE: The author desires to express his thanks to Major Joseph W. Smith, Jr., Medical Corps, U. S. A., for his criticism and assistance.

The Public Health Service as a Career

THE salaries . . . are not munificent, and the chief reward of public health service is to be sought in the work itself. There is a great fascination for many people in scientific enquiry and investigation in which the practice of preventive medicine provides unlimited scope. To watch the effect of one's procedure upon the progressive health of a community provides one with a solid satisfaction equal to any that can be found in other branches of practice. More fields remain to conquer, so that there is ample scope for the exercise of unlimited genius yet. Preventive medicine has long come into its own, although forty years ago and less it was the Cinderella of the profession. Public health means more and more every year to the man in the street who, while he may speak with reverential awe of the wondrous operations of some great surgeon, appreciates far more highly the measures which render such an operation unnecessary or prevent the occurrence of a disease, and there is no doubt whatever that the public health service is making good its promises, and will undergo considerable expansion yet.—Harold Kerr, M.D., *Med. Off.*, Sept. 6, 1930, p. 97.

Incubation of the Completed Kahn Test

NATHAN NAGLE AND JOHN LAZAROV

Health Division Laboratories, Department of Public Welfare, St. Louis, Mo.

IN the standard Kahn test¹ the reactions are read immediately after the patient's serum and antigen are brought into intimate contact during the 3-minute shaking period. Incubation periods which are part of the complement fixation and certain precipitation procedures are not required to bring about visible flocculation in the Kahn test. Because incubation periods were part of Kahn's original procedure (1922) and of tests based on the hemolytic systems, many workers erroneously make this step a part of the standard Kahn technic. This article deals with experiments to determine what part prolonged incubation of the completed Kahn test plays in influencing the final results.

The standard method of reading the Kahn reaction (immediately following the shaking period) was compared with methods in which prolonged incubation periods were used. Overnight incubation at icebox (5° to 7° C.), room (about 22° to 28° C.), and incubator temperature (37.5° C.), were employed in these experiments. The incubation periods varied from 16 to 20 hours.

Six hundred and ninety-three completed Kahn tests were incubated overnight at icebox temperature (5° – 7° C.), and the reactions compared with the standard method of reading. Table I shows that prolonged incubation at this temperature makes the test considerably more sensitive. Twenty-one per cent of the negative reactions became positive after this incubation period. Clinical data secured on some of the positive reactions gained showed them to be so-called

TABLE 1

INCUBATION OF 693 KAHN REACTIONS OVERNIGHT AT ICEBOX TEMPERATURE

No. Specimens	Standard Method	Icebox Temperature	No. Specimens	Standard Method	Icebox Temperature
124	++++	++++	2	+	++++
8	++++	+++	6	+	+++
5	+++	++++	7	+	++
29	+++	++++	8	+	+
4	+++	++	7	—	++++
3	++	++++	5	—	+++
4	++	+++	8	—	++
6	++	++	34	—	+
1	++	+	432	—	—

"false positives." Some of the "weaker" positive reactions gained were secured from individuals who have had intensive anti-syphilitic treatment.

Of 521 tests incubated overnight at 37.5° C., 37 per cent of the positive reactions became negative after the incubation period. One negative reaction became 1 + after this period. The majority of these reactions can definitely be classed as "false" negative reactions. Table II shows the results obtained in this group of tests.

TABLE II

INCUBATION OF 521 KAHN REACTIONS OVERNIGHT AT 37.5° C.

No. Specimens	Standard Method	37.5° C. Temperature	No. Specimens	Standard Method	37.5° C. Temperature
46	++++	++++	2	+++	+
23	++++	+++	12	+++	-
1	++++	++	8	++	-
4	++++	+	1	+	+
10	++++	-	21	+	-
8	+++	+++	1	-	+
2	+++	++	382	-	-

Nine hundred and sixty-five tests were incubated overnight at room temperature (22°-28° C.). The readings at the end of this period corresponded very closely to the results obtained by the standard method. There is a tendency for the cholesterol to precipitate out of solution at the end of this period. The presence of this cholesterol simulates the specific precipitate so closely that it may be read as a positive reaction. Three 1 + reactions became negative at the end of the incubation period and two negative reactions became 1 + and 2 + respectively. Table III shows that reactions fluctuate in either direction, although the general tendency is for the reactions to become weaker at the end of the incubation period.

TABLE III

INCUBATION OF 965 KAHN REACTIONS OVERNIGHT AT ROOM TEMPERATURE

No. Specimens	Standard Method	Room Temperature	No. Specimens	Standard Method	Room Temperature
213	++++	++++	1	+	++++
5	++++	+++	2	+	++
35	+++	+++	39	+	+
1	+++	++++	3	+	-
1	+++	+	1	-	++
5	++	+++	1	-	+
11	++	++	643	-	-
4	++	+			

CONCLUSIONS

When the completed Kahn test is incubated overnight at room, icebox, or incubator temperatures, the character of the reactions varies materially from those obtained in reading the test in the standard method. Incubation of Kahn tests overnight at icebox temperature tends to give false positive reactions. Overnight incubation at 37.5° C. tends to dissolve formed precipitates and give negative reactions. Incubation at room temperature has comparatively little effect on Kahn reactions. It appears that most reliable results are obtained when the Kahn test is read directly after the 3-minute shaking period.

Psittacosis

WE now have a record of 74 focuses of infection which gave rise to 169 cases, with 33 deaths, from November 23, 1929, to May 7, 1930. These cases occurred in 15 states and the District of Columbia and do not include 16 laboratory infections, with 2 deaths, nor 12 probable cases which were removed from two merchant ships entering our ports following exposure aboard ship to parrots purchased in Germany and Brazil. . . . Nevertheless, it was deemed desirable to determine the occurrence of illness among a control group of persons who had recently acquired apparently normal parrots. With this end in view, 103 parrots, a random sample, were traced to their ultimate destinations. These birds were sold by the same dealers and during the same time, November and December, 1929, as were many of the incriminated parrots. Eighty-eight of the 103 parrots were described as apparently in perfect health, and among the families exposed to them there was not a single suspected illness reported.

The remaining 15 parrots of the series either had died or were killed on account of illness. One of these birds had given rise to 6 cases of typical psittacosis. There was no human illness reported from contacts with the 14 other sick birds, of which the character of illness is of course unknown.

Parrots were associated with the development of 55 focuses of disease, parakeets with 4, "love birds" 3, canaries 3, while in 9 outbreaks exposure was to multiple species.—Charles Armstrong, Surgeon, U. S. P. H. S., *Pub. Health Rep.*, Aug. 29, 1930.

Mobile Milk Laboratories

THOMAS PARRAN, JR., M. D., F. A. P. H. A.

Commissioner, New York State Department of Health, Albany, N. Y.

THE New York State Department of Health was authorized by the last legislature to make a survey of the milk supply of the state. This survey will include inspections of farms, milk plants and ice cream plants and also laboratory examinations of milk and cream as delivered to the plants and as delivered to the consumer. This work is being carried on with the coöperation of the local health departments.

The purpose of the survey is to check up on the sanitary quality of milk and cream reaching consumers in the state and to develop a plan for a more complete, effective, uniform and practical control of this supply. The results of the survey will serve as a guide for future milk control work throughout the state.

In order effectively to carry out the survey program, a laboratory for the examination of milk and cream is necessary. Two mobile laboratories are now in operation. They are equipped to make both standard plate counts and direct microscopic counts. Standard street car type buses are used with all except the driver's seat removed. The clear space inside the bus is about 7' wide, 18' long and 6' high for the installation of laboratory equipment. Laboratory benches are installed along each side and the back. A sink with running hot and cold water is

provided for washing laboratory glassware. A small water storage tank under air pressure serves as a source of water supply. Air pressure and water connections are located in the outside so that filling station service may be used. The water is heated by electricity and is stored in an insulated tank resembling a thermos bottle.

An electric meter is installed and long lead-in wires are provided for connecting with an electric power circuit. In this way, power is supplied when the bus is not running. This provides 110 volt current for operating the steam pressure sterilizer, sterilizing oven, Babcock tester for making butter fat determinations, heater for heating the bus when it is not in motion, water heater, refrigerator, fans and lights. The laboratory equipment includes an electric incubator operated by storage batteries which is automatically kept at body temperature for growing the bacteria found in milk.

Also included in the equipment are microscopes, an electric refrigerator, special gas burners supplied with compressed natural gas, and the necessary chemicals, glassware and supplies for carrying on various bacteriological and chemical tests.

All samples of milk and cream are either plated or examined under the microscope to determine the bacterial counts.

These laboratories will be stationed in each of the larger cities of the state and from these centers the survey will extend into the surrounding territory. Stops of either 1 or 2 weeks will be made, the length of the stay depending upon the amount of work to be done in each locality.

For the present, these laboratories will be used in carrying on the milk survey of the state. Eventually they will act as service laboratories, working in coöperation with health departments, milk plants and dairymen.

The Fatality of Scarlet Fever

A STUDY of scarlet fever in England confirms the general impression that for some 50 years past the fatality of the disease has been declining steadily. Here and there a higher mortality than expected is observed, but these few cases do not have a marked influence on the general trend.

Some of the reports are very striking—in one town, 210 cases with 1 death, in another an epidemic (number of cases not stated) with no deaths. In Liverpool, there has been a decline from 9.3 mortality per 100,000, in 1919, to 1.7 in 1929, though there were two years intervening in which the death rate had no decline. From a number of other towns there are reported epidemics with a general mortality of slightly over 1 per cent.

The reports do not seem to give any safe ground for forecasting, but they demonstrate certainly that scarlet fever is now a much milder disease than it has been in the past.

THE AIRPLANE AND YELLOW FEVER

IT is well known that contagious disease travels at the rate of human transportation. Modern developments have changed many of our conditions, in some cases for the better, but in many for the worse, so our ideas and practices must be modified to meet these.

The substitution of steam for sail has brought us into very much closer contact with every part of the world, and the diseases indigenous to one country are becoming common possessions of all countries engaged in commerce.

The most recent problem is the airplane, and this has come up for discussion before the International Office of Public Hygiene, which has been attempting to draft a program to prevent the spread of yellow fever by this means. While it has been shown that the carrying of adult mosquitoes on vessels is not the danger it was once supposed to be, nothing is known of airplane conditions, though there is a rather general belief that a real danger exists. Apart from the carrying of infected insects, passengers may well carry the infection. To avoid this danger, an article in the regulations imposes on passengers from infected areas a period of observation of 6 days before embarkation, and a further period of observation of 6 days upon arrival. As all studies so far have shown that the infective period of yellow fever is only 3 days, it is possible that these proposals may be modified. The Conference of 1926 fixed 5 days as the infective period on the suggestion of Dr. Chagas, and at the last meeting of the Quarantine Com-

mission on Aerial Navigation, May 14, 1930, modification was opposed until the delegates from South America who were not present could have an opportunity of discussing this point.

There has already been established in South America a hydroplane service route along the coast across the yellow fever regions, for which the points of departure and landing are entirely on the sea. This may lessen the danger, but certainly does not do away with it, in view of the embarkation and landing of passengers. The matter is one of extreme interest and possibly great importance from the public health standpoint. New methods of transportation require new studies and new rulings.

THE AMERICAN HEALTH OFFICER AND HIS EUROPEAN BROTHER

THIS summer, more than a hundred American public health workers visited the International Hygiene Exhibition at Dresden and called on many of their confrères in European health services. What did they observe? What did they learn? Certainly they could not have avoided an observation which to one traveler at least seemed very obvious—that American health officers are particularly fortunate to have a country like the United States in which to work. Their job is made infinitely easier and more effective because the standard of life of the great mass of people is on a relatively high level. In fact, the higher standard of living may be what has made possible most of the health work so characteristic of America today; it is part of the service which the American standard requires!

The countries of central, southern and eastern Europe present a striking contrast in this regard. To a very large extent, they appear to have overcome the immediate effects of the war. Nevertheless, one cannot avoid the conclusion that their populations are still suffering seriously from a poverty which verges very close on destitution. Housing, with the exception of a few isolated instances, as in Berlin, Vienna and Rome, is generally unfavorable to the development of good health. Illiteracy is far too prevalent, while undernourishment and malnourishment are frankly in evidence. Under conditions of this sort, it is amazing that health officers have been able to accomplish as much as they have in many European countries. Imagine the difficulties that are met with in developing a campaign against tuberculosis in the manner that it has taken hold with us. We emphasize the instruction of the people in personal hygiene and prescribe adequate nutrition, rest, good housing, and plenty of sunlight and fresh air as

preventives. Or consider the essentials in reducing high infant mortality. They call for much the same prescription plus the enforced rest of the mother during pregnancy and the necessary freedom from arduous toil later to permit breast feeding for a large part of the first year of the baby's life. To launch an effective tuberculosis or infant mortality campaign in Roumania or Greece, for example, is close to wishing the job of Tantalus on a helpless and impoverished people. Health officers can accomplish little under conditions such as prevail in most European countries.

Public health, in other words, does not stand alone. It is dependent upon the whole pattern of life. It exists as part of the life which a people can afford. It flourishes when the economic level is high; it is retarded almost to the point of extinction when standards in general are low. No one will ever be able to analyze all the factors that have entered into the extraordinary extension in life expectation and in freedom from disease which characterize the average American. Many elements have gone into making our country what it is from a public health standpoint; but obviously not the least has been the constantly advancing level of well-being for the common man and his freedom from destitution and its consequences.

We have been particularly fortunate that from the beginning it has been an article of our political faith not to stratify our population into classes. The working people made the nation, shaped the direction of government so that it included health protection, and, moreover, generated the money income which pays for such protection. On the other hand, many European countries still suffer from the implied assumption that those who work with their hands must be poor, that they belong to a lower order of nature, destined with their children to remain in that station in life to which they were born; and, worst of all—not entitled to the equal benefit and protection of governmental service. So long as such a philosophy of government holds, and unfavorable economic conditions characterize the great mass of people, death and sickness rates will continue to be high. A vicious circle is established—poverty leads to inability to support public health work and this, in its turn, makes it difficult to escape from the very unfavorable situation to which much of the poverty is due.

Health officers in the States should, therefore, realize how fortunate they are in dealing with a relatively well fed and well clothed, literate and progressive population. There is scarcely a limit to the amount of service that is available for development under such conditions. Public health work costs money. It is available to us and has proved its worth. There is little excuse for some of the unfavorable

health situations that we still have with us. The visit of our health officers to less fortunate European cities should stimulate a new spirit of activity and progressive work in many corners of our country.

VACCINE AND VACCINATION

A WRITER in the *Medical Officer* protests against the use of the words "vaccine" and "vaccination" for any material or immunization process except calf lymph and its use against smallpox, holding that it leads to confusion and misunderstanding.

The word vaccine is derived from the Latin "vaccinus," of or from cows, this in turn being derived from "vacca," a cow. According to the etymology, the term should be limited to calf lymph prepared for protection against smallpox.

An examination of a number of American dictionaries makes this perfectly clear, but all give as a secondary meaning any substance for preventive inoculation. One of the most advertised dictionaries even includes the word "bacterin" in its definition, though we believe that this term was originated by a certain firm as a trade name.

In these days when the study of Latin and Greek is decadent, the derivation of words means little to the average reader or writer. While our sympathies are entirely with the writer in the *Medical Officer*, we must point out that usage determines the meaning and use of words. Many examples can be given showing complete changes from the original meaning; for example, "idiot," derived from the Greek word meaning a private person, and "manufacture," meaning to make by hand. At present, when manufactured articles are made by hand, the fact is usually advertised. We might now well define manufacture, to make by machinery. Language grows, and words change in meaning, but this is no excuse for the barbarisms which are so common.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Public Health Administration in Syracuse, N. Y.—In 1923 diphtheria immunization work began in earnest in Syracuse. From that year through 1929, there have been given 27,372 protective treatments. Except during 1924 no effort has been made to re-Schick the children to determine the extent of immunity conferred. However, of the 19 deaths which have occurred in Syracuse during the past 5 years, only 1 child among those receiving the full course of treatment contracted diphtheria and died.

In 1929, three treatments of toxin-antitoxin were administered to 8,023 children, of which number 4,255 were 5 years of age or under. In 1929 there were only 27 cases of diphtheria reported, which is less than half the number reported in 1928.

Syracuse has not had a single case of smallpox during 1929 and it is now 41 years since a death occurred from this disease.

In 1929 there were known to the Health Department 716 active cases of tuberculosis compared with 1,076 in 1928. Of the deaths in 1929, 81.4 per cent were reported as cases prior to their death. It was also found that 37.2 per cent were reported a year or more before death of the patients.—George C. Ruhland, *Annual Rep.*, Dept. of Health, 1929.

Typhoid Fever Spread by Lobster—During the month of July, 1929, there were 9 cases of typhoid fever in four neighboring communities, epidemiological investigation indicating that the common food had been lobster

coming from the same source of supply but distributed through four stores.

A man employed in the room in which the lobsters were handled, sorted, and stored, had died of typhoid fever early in July. The empty barrels in this storeroom were not cleaned with any regularity but were foul with slime and filth and formed ideal culture mediums for any chance contamination.

While it is not possible to state just how the lobsters became infected, it is presumed that the lack of sanitation at this packing house was the direct cause of the food becoming contaminated. It is believed that the part of the food actually consumed, that is, the lobster meat, had not been originally contaminated, but that contamination from the barrels upon the lobster shells had been transferred from the shells to the meat by the fingers of handlers in the course of preparation or consumption.—G. W. Anderson and C. L. Scamman, *Typhoid Fever Apparently Spread by Boiled Lobster*, *J. Prev. Med.*, 4, 405 (Sept.), 1930.

Diphtheria Immunization in Detroit, Mich.—The Health Department continues to carry on its program of prevention solely through the medium of the family physician. During the past two years, no immunizations have been given by the Health Department, not even to indigent families. The Health Department reimburses the physician at the rate of 50 cents for each dose of toxin-antitoxin for the children of indigent or near indigent families.

During the summer months of July and August, 50 school nurses did house-to-house canvassing in districts where

the diphtheria death rate is above the city average. There were 23,748 children whose parents were interviewed. Of this number 9,084, or 38 per cent, had previously received three doses of toxin-antitoxin. Of the remaining 14,664 children whom the nurses have attempted to have immunized, 5,777, or 39 per cent, have completed the course of treatment and the reports are not as yet complete. This brings the percentage of immunized children in these districts up to 62.6.

A combination of summer vacations and hard times has apparently delayed familial coöperation to some extent. Among those interviewed, 3,080, or 21 per cent, refused to have their children protected immediately because they were going away for the summer or could not take care of it on account of illness in the family. Others would not go to the family physician because they felt that they could not afford the preventive service and were unwilling to accept charity. Thirty-eight per cent definitely refused to consider diphtheria protection for their children.

It is encouraging to note that of the children immunized due to the nurses' educational program, 67 per cent were under 6 years of age. All of the immunizations were given in the office of some, one of the 900 coöperating physicians, the nurses having been provided with complete lists of all such physicians. —*Detroit Health Dept. Weekly Rev.*, 11, 38 (Sept. 20), 1930.

Health Administration in Dayton, O.—In 1929 the per capita expenditure of the Health Department amounted to 62.4 cents compared with 44 cents in 1920. The Commissioner of Health is responsible to the Director of Public Welfare, there being no Board of Health nor advisory council. Effort is made to inspect and score the 2,565 dairies producing milk for the city each year. The 58 milk plants in which 99½ per

cent of the supply is pasteurized are regularly supervised by inspection and by laboratory analysis of the product.

Examination is made in the laboratory of utensils, such as spoons, forks, or glasses which are taken from food establishments, wrapped in sterile towels and brought to the laboratory for examination. This system is proving a very effective method of checking the cleanliness of eating and drinking utensils and bacteria count. The results of this checkup, which has been in use since 1925, are published monthly and furnished to all who desire them.—A. O. Peters, Health Commissioner, Dayton, O.

Whooping Cough—The positive organism in whooping cough was isolated by Bordet and Gengou 24 years ago and it has been 14 years since Chievitz and Meyer developed their simple method for early diagnosis. Whooping cough can now be diagnosed before the lymphocytosis and whoop. Two hundred cases which have been seen in private practice have been analyzed with respect to bacteriological findings. The diagnostic plate was positive in all but 1 of 53 patients in the catarrhal stage. Of 107 cases in the paroxysmal, 70 had positive plates representing 65 per cent of the total in this group. Of 40 cases studied bacteriologically in the period of decline, none showed positive plates. —L. W. Sauer, L. Hambrecht, Whooping Cough, Early Diagnosis by the Cough Plate Method, *J. A. M. A.*, 95, 263 (July 26), 1930.

Health Examination in Newark, N. J.—In 1929 the personnel of the Health Department totaled 235, organized into ten functional divisions, including: Administration (18), Communicable Disease (21), Venereal Disease Control (19), Tuberculosis (15), Child Hygiene (29), School Health Service for Parochial Schools (9), Laboratory (31), Food (45), Sanitation and

Plumbing (46), Dispensary (22).

The total expenditure of the Health Department amounted to \$560,000 or \$1.27 per capita, including 6 cents for plumbing inspection and 9 cents for the relief of sick poor. A total of 1,005 cases of tuberculosis with 441 deaths indicates better than average reporting for cities of this class.—C. V. Craster, Health Commissioner, Newark, N. J.

Children's Fund of Michigan—On April 30, 1930, the first year of the Children's Fund of Michigan was completed. Senator James Couzens of Michigan made a gift of \$10,000,000.00, dedicated to the welfare of children. Dr. Hugo A. Freund is President of the Board of Trustees and William J. Norton is Secretary of the Board.

There was organized in September, 1929, a division of child health under the administration of Dr. Bernard W. Carey, under whose direction there has been established a Child Health Demonstration in Menominee County. Two consolidated health units have been established in the lower peninsula, each of which includes four counties which, for the present, are without adequate economic resources to finance necessary health service individually.

A special oral hygiene program of extensive character has been inaugurated as well as a county nursing program, mothers' classes in child hygiene and a program of health education. In

initiating its program, the Fund has given special attention to research problems in dental hygiene, to the care of dependent and delinquent children and child guidance clinics.—*First Annual Report of the Children's Fund of Michigan*, Detroit, June, 1930.

Meningitis in Detroit, Mich.—Meningococcus meningitis has been epidemic in Detroit since 1928. In June, 1930, the outbreak was still continuing without evidence of early limitation. Fulminating infections were not encountered until four months after the first increase in the number of reported cases. They continued relatively uncommon during the first year of the epidemic, increased during the second year, and were most numerous during the early part of the third.

Abortive forms of meningococcus infection were encountered during the epidemic period, clinically corresponding to a mild nasopharyngitis. The disease may be limited to a septicemic stage, but is more commonly recognized as an infection of the meninges. Meningococcus meningitis may evidence a rapidly fatal fulminating course, or, more commonly, a slower evolution, or it may, in the absence of specific treatment, lapse into a chronic state with subsequent acute recurrence—J. E. Gordon and J. F. Norton, *Meningococcus Meningitis in Detroit in 1928-1930*, *J. Prev. Med.*, 4, 339 (Sept.), 1930.

LABORATORY

C. C. YOUNG, D. P. H.

A STERILE DISPENSING FUNNEL

G. D. CUMMINGS

Michigan Department of Health, Lansing, Mich.

THE media division of this laboratory has used the sterile tubing funnel shown in the figure for a number of years for dispensing mediums into tubes or flasks which cannot be sterilized after the addition of enrichment substances.

Included in this group are such mediums as plain and chocolate blood agar, ascitic fluid, carbohydrate semi-solid agar, and cystine glucose agar. The procedure in the preparation of any of the above ordinarily calls for the addition to the sterilized and cooled agar or broth base of the sterile enrichment agent. Unless a suitable apparatus is available for dispensing the medium, the latter must be transferred from bottle to tube by direct pouring. This method is unsatisfactory because continual flaming usually cracks the bottle neck, and as the agar or broth to be dispensed is sometimes moderately hot the direct handling of the container is uncomfortable.

The funnel here shown is made of sheet copper and tin lined. The top is soldered on so that the opening into the funnel consists of a soldered brass collar $2\frac{1}{2}$ " in diameter in the center of the top surmounted by a tightly fitting brass and monel metal cap. A Mohr pinch-cock, a length of rubber tubing, and a straight sided filling bell complete the outfit.

The particular funnel shown was designed to contain 1,000 mils and cost

\$2.00, including the materials and labor.

The funnel is rinsed out and washed immediately after use so that no opportunity is available for agar or gelatin to solidify inside. The filling bell is freshly plugged and the apparatus sterilized for 30 minutes at 15 lb. pressure. Once sterilized, the funnel may be placed in a cupboard until used again. Experience has shown that it

will remain sterile indefinitely.

With a battery of such funnels, the task of dispensing enrichment mediums

into tubes, flasks, or Blake bottles may be performed with great ease and excellent asepsis.

AN AID TO MORE ACCURATE COLONY COUNTING

M. O. ROBINSON, V.M.D.

Director of Laboratories, Scott-Powell Dairies, Philadelphia, Pa.

IN routine laboratory work much depends upon the individual who handles the colony counting. It has frequently come to our notice that serious mistakes are often made, and may go undetected by those in charge, due to the impossibility of making a thorough check of all the plates counted.

The workers are faced with the task of turning out accurate counts, and, at the same time, going through the monotonous routine of counting hundreds of plates each day. When we consider that practically all counts are multiplied by some dilution factor, the

possibility of grave errors in the final reports assumes large proportions.

Actually to check the work is no small problem, and probably very little checking is done.

In order to relieve the monotony, and to increase the rapidity and accuracy with which counts can be made, we have devised an electrically operated contact pen. This serves the twofold purpose of aiding the worker to turn out more accurate counts, and, at the same time, to leave upon the plate a definite picture showing the completeness with which the work was done.

The outfit consists of an electric tally apparatus, a special pen holder, and an ordinary pen point. Current is obtained directly from the lighting circuit.

Within the barrel of the pen holder there is a contact arrangement which completes the circuit when the point of the pen is pressed against the glass dish. In this way, we have the count recorded upon the tally apparatus, and the colonies which have been counted definitely marked.

Our plates are counted by placing them, inverted, over a Stewart counting chamber. The operator marks the colonies with the pen, using ordinary writing ink. In this way, a mark is

made over the colony at the time of counting, which serves as a check on the number counted, and shows at a glance the completeness with which the work has been done. This has been of great assistance in checking where large numbers of plates are counted each day, as it leaves a definite record upon each plate counted.

The adoption of the electrical counter seems to be a step ahead of other methods in use. With the count being recorded during the marking process, it reduces the possibilities of error to a minimum. We find that workers are able to count for hours, without experiencing the mental fatigue and inaccuracies of other methods.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Health Conditions in India—The birth rate for India in 1927 was 35.27 per 1,000, which was above the ratio of the two previous years; the death rate was 24.89, representing a fall from 1926. The infant mortality rate was 167 per 1,000 live births. Over 8,000,000 persons were treated for malaria in 1927. Respiratory diseases accounted for the highest death rate of the country, being between 8 and 16 per 1,000 population.

Tuberculosis varied from 8.4 per 1,000 for Kashipur in the United Provinces to 1.6 in the city of Bombay. There were 780,000 anticholera inoculations performed in 1927 in Bengal, which had suffered a mortality of 120,000 or an increase of about twice the usual mortality. Plague had the lowest mortality in 1927 for the last 30 years.

There has been a steady rise in mortality from smallpox since 1921. There were 2,342 deaths from rabies. The

total number of patients treated in state and private civilian hospitals and dispensaries came to over 4,600,000.—*J. A. M. A.*, 95: 603 (Aug. 23), 1930.

The Development of Maternity Work in China—The urgent need for midwifery training in China has come to the attention of the government. China at present has deplorably high maternal and infant mortality rates as compared with other countries. The maternal mortality is 15 per 1,000 and the neonatal mortality at least 250 per 1,000. Midwives have been a part of the social economy for years but only sporadic attempts have been made to control and register them.

Recently, a real attempt has been made and a board formed, under the Nationalistic Government, to draw up plans and regulations for schools of midwives. It is estimated that there are

200,000 old-type and 500 modern-trained midwives. To make registration possible, requirements will have to be lowered to include all the former groups. Under present conditions, China will have to be content to register about 85 per cent of those acting as midwives. But a real beginning has been made and the work will undoubtedly progress steadily in spite of political changes.—J. P. Maxwell, *Brit. M. J.*, 2: 184-185 (Aug. 2), 1930.

Life and Death in Harlem—A study of the 21 sanitary districts comprising the North Harlem district of New York City showed that the inhabitants have hazards two to three times as great as other inhabitants of the city. For every major cause of death, figures for North Harlem exceeded Manhattan and the city as a whole.

The birth rate for North Harlem is at least 5 per cent above that of New York City, the rates being 23.0 for Harlem; 24.4 for Manhattan; and 21.9 per 1,000 population for New York City. The infant mortality rate is 111 per 1,000 births, an excess of 65 per cent over the average city rate. The pneumonia rate is exceptionally high, 256 per 100,000. Pulmonary tuberculosis averaged 368 deaths annually with a rate of 193 per 100,000 population for the 5-year period 1923-1927. Maternal mortality in Harlem is 10.1 compared with 4.8 in Manhattan and 5.1 per 1,000 live births in New York City.

The diphtheria rate in Harlem is not in excess of the general figure, but whooping cough is in the ratio of 2 to 1 in excess for the colored. North Harlem shows a lower suicide rate than Manhattan, and a point lower than that for the city. The homicide rate for Harlem is almost double that for Manhattan, and more than 3 times the city's rate. The cancer rate is more favorable than for Manhattan. Puer-

peral diseases and malformations at birth have a higher rate but diarrhea and enteritis have a rate 2 points below Manhattan.

There were 1,839 deaths from pulmonary tuberculosis in North Harlem from 1923 to 1927, the rate for the 5-year period being 193 per 100,000, compared with 115 for Manhattan and 81 for the city. The rate for Harlem gradually increased over the 5-year period while in Manhattan it remained almost constant and in the city showed a gradual decline.—W. B. Nathan, *J. Outdoor Life*, 27: 541-544 (Sept.), 1930.

Cancer Record for 1929—The cancer death rate of 49 American cities increased from 71.6 per 100,000 population in 1906 to 117.8 in 1929, representing an average annual increase of about $2\frac{1}{2}$ per cent. The number of cancer deaths in Massachusetts, where possibly the most determined effort against cancer control is in progress, increased from 5,611 in 1928 to 5,672 in 1929, in Maine, from 1,069 in 1928 to 1,120 in 1929.

Statistics for 146 cities showed the cancer rate stationary for the past two years, 114.4 per 100,000; however, the actual number of cancer deaths in these cities increased from 43,426 to 44,262. Of these 146 cities, Portland, Me., reported the highest cancer death rate in 1929, 187.5 per 100,000 population. In the five cities with populations over 1,000,000 or more, the number of cancer deaths rose from 16,120 in 1928 to 16,481 in 1929. Philadelphia reported a rate of 126.3 in 1929; Los Angeles, 124.9; New York, 113.9; Chicago, 106.1; and Detroit, 73.1.

In 1928, cancer had reached the status of being the third leading cause of death in the United States Registration Area, the rate being 96 per 100,000 according to the U. S. Bureau of the Census. The cancer rate for 17 Euro-

pean countries for the period 1921-1927 showed a range of from 141.9 per 100,000 for Switzerland to 61.8 for Italy. For the same 7-year period in 9 non-European countries, the rate reached a maximum of 90.6 per 100,000 in Australia, and a minimum of 12.3 for the Republic of Salvador. In practically all of these countries, the cancer death rate continued to increase from year to year during the period dealt with.

Two illustrations show the nature of the local cancer problem as to organs affected. The proportion of deaths from cancer of the buccal cavity in the total mortality from all forms of cancer varied, for males, from 50.4 per cent for Ceylon, to 2 per cent for Chile. The proportion for the white population of the United States was 6.1 per cent; for American negroes, 5.6 per cent; for American Indians, 5.5 per cent; and for American Chinese, 2.3 per cent. The range for cancer of the stomach and liver, for males, varied from 83.4 per cent for Japan to 22.5 per cent for Ceylon. United States showed proportions from 44.8 per cent for the white population to 59.6 per cent for American Chinese.—F. L. Hoffman, *Spectator*, 125-3-20 (Aug. 14), 1930.

MORTALITY STATISTICS: 1929

Pennsylvania—The Department of Commerce announces that there were 117,365 deaths in Pennsylvania during 1929 as compared with 119,607 in 1928.

For the 4-year period 1926 to 1929, marked decreases were shown for measles, from 1,058 deaths in 1926 to 367 in 1929; typhoid and paratyphoid fever, from 357 to 199, whooping cough, from 927 to 575, and diphtheria, from 800 to 689. Deaths from tuberculosis, all forms, diarrhea and enteritis, under 2 years, and congenital malformations and diseases of early infancy showed continual decreases from 1926 to 1929.

The deaths reported from meningococcus meningitis in 1928 and 1929

were nearly 3 times as many as in 1926 and 1927. The four outstanding causes of deaths were diseases of the heart, pneumonia, all forms, nephritis, cancer and cerebral hemorrhage.

While the deaths from all accidental unspecified external causes showed a total increase of only 83 in 1929 as compared with 1928, those from automobile accidents increased by 277 and from machinery accidents by 38; these increases were principally offset by decreases in deaths from drowning, mine accidents, and railroad and street car accidents.

Wyoming—There were 2,010 deaths in Wyoming during 1929 as compared with 2,155 in 1928.

A comparison of the deaths in 1929 with those in 1928 showed decreases in such important causes as whooping cough, influenza, tuberculosis, all forms, cancer, cerebral hemorrhage, pneumonia, all forms, and nephritis.

Increases in deaths from 1928 to 1929 appeared for syphilis, appendicitis and typhlitis, and diseases of the heart; for the last cause the increase has been continuous from 1926.

The deaths from accidental and unspecified external causes increased from 253 in 1928 to 284 in 1929, the greatest increase among these appearing for automobile accidents (59 to 73).

Massachusetts—Massachusetts has reported 51,916 deaths during 1929 compared with 51,034 in 1928.

Diseases of the heart alone caused over one-fifth of all deaths reported in the state and show an increase for each succeeding year.

Deaths from influenza and its associated disease, pneumonia, were 900 more in 1929 than in 1928, and this combination of diseases was the cause of the second greatest number of deaths.

For the 4 years 1926-1929, cancer has shown a continuous increase from year to year and now ranks as the second single greatest cause of death.

The diseases mentioned above, with

cerebral hemorrhage and softening, and tuberculosis, which has shown a decrease for each of the 4 years reported, caused approximately three-fifths of all of the deaths reported for the year. In addition to tuberculosis, decreases from 1926 to 1929 were shown for diarrhea and enteritis, under 2 years of age, nephritis, and congenital malformations and diseases of early infancy.

In the epidemic diseases, decreases were in measles, scarlet fever, and whooping cough.

Among accidental and unspecified external causes, deaths from drowning decreased from 315 in 1928 to 254 in 1929. Deaths due to accidental falls increased from 731 to 772. There was a slight decrease in the number of deaths due to street car accidents, and the number due to automobile accidents increased from 724 to 781, a continuous increase for each of the 4 years.

Minnesota—There were 25,092 deaths in Minnesota during 1929 as compared with 25,977 in 1928.

Though the total number of deaths in this state has remained practically the same for the 4 years 1926–1929, there have been a number of decided changes in the diseases causing death. For the years 1929 and 1928, the numbers of deaths due to influenza were nearly double the numbers reported from 1926 and 1927. These large increases and the increase due to deaths from automobile accidents more than offset the decrease due to deaths from other causes. The number of deaths from measles increased from 13 in 1928 to 84 in 1929, but this latter figure compares very favorably with the 175 deaths from this disease in 1926. The great decrease in deaths from diphtheria during the 4-year period is very satisfactory and is in step with similar reports from other states. Cancer is each year taking a larger toll of deaths and next to diseases of the heart is the outstanding cause of death.

The important diseases for which less deaths were reported in 1929 than in 1928 were acute anterior poliomyelitis, 59 to 6; diarrhea and enteritis, under 2 years of age, 198 to 135; puerperal causes, 280 to 201.

The decrease in deaths from railroad and street car accidents was more than made up by the deaths from automobile accidents.

Vermont—The Department of Commerce announces that there were 5,295 deaths in Vermont during 1929 as compared with 4,888 in 1928.

The causes which took the greatest toll of life were those diseases which affect persons of older ages, namely, diseases of the heart (1,092), cerebral hemorrhage and softening (516), cancer (465), and nephritis (445). The first two causes alone were responsible for nearly one-third of the deaths in the state.

The deaths from influenza in 1929 more than doubled the number in 1928, and other increases were from pneumonia, all forms, and diarrhea and enteritis under 2 years. Decreases were shown for tuberculosis, all forms, and diabetes mellitus.

Among the deaths from accidents, decreases appeared for drowning, machinery accidents, and automobile accidents, and increases for burns and shooting.

Kentucky—There were 31,109 deaths in Kentucky during 1929 as compared with 30,390 in 1928.

Very appreciable decreases in deaths in 1929 as compared with 1928 appeared for typhoid and paratyphoid fever, measles, syphilis, pellagra, diarrhea and enteritis, under 2 years, and congenital malformations and diseases of early infancy, and comparatively slight decreases were shown for tuberculosis, all forms, cancer, pneumonia, all forms, and nephritis.

Notable increases were those from influenza, which in 1929 caused nearly twice as many deaths as in 1928, and

from meningococcus meningitis, which more than doubled the number of deaths in 1928. Other increases were reported from scarlet fever, whooping cough, diabetes mellitus, and diseases of the heart, the last of these being the outstanding cause of death.

Total deaths from accidental and unspecified external causes showed only a slight increase in 1929 over 1928, but the increase in automobile accidents was large (342 to 389) and accidental shooting and railroad accidents also showed a larger number in 1929; a noticeable decrease was reported in deaths from mine accidents.

Michigan—Michigan has reported 56,118 deaths during 1929 as compared with 54,794 in 1928.

The total increase in deaths in 1929 as compared with 1928 was 1,324, nearly half of which was accounted for by the appalling increase in deaths from meningococcus meningitis, from 189 to 812, and two-thirds of these deaths occurred in Detroit alone (542). Other increases were shown for diphtheria, influenza, diseases of the heart, appendicitis and typhlitis, cancer, and diabetes mellitus; for the last two of these causes the increase was continuous from 1926. The deaths from suicide also increased during each year for this period.

Notable decreases from 1928 to 1929 appeared for measles, scarlet fever, pneumonia, all forms, and nephritis.

The deaths from accidental and unspecified external causes increased in

1929 as compared with 1928, the principal increases appearing for accidental drowning and automobile accidents; decreases were shown for railroad and street car accidents.

Kansas—The Department of Commerce announces that there were 19,392 deaths in Kansas during 1929 as compared with 20,946 in 1928.

While deaths from typhoid and paratyphoid fever and measles showed increases in 1929 over 1928, there was a very big decrease from 1926, and whooping cough, which showed a decrease from 1928 to 1929, 91 to 80, was responsible for 120 deaths in 1926.

The most notable decrease in deaths in 1929 as compared with 1928 was that from influenza from 1,472 to 869; other very important decreases were from tuberculosis, all forms, cancer, diseases of the heart, pneumonia, all forms, diarrhea and enteritis, under 2 years, nephritis, and cirrhosis of the liver.

Among increases in deaths were those from meningococcus meningitis, scarlet fever, and diabetes mellitus.

The increase of 131 deaths from 1928 to 1929 from accidental and unspecified external causes was more than accounted for by increases in deaths from accidental drowning (75 to 85), accidental shooting (41 to 70), mine accidents (16 to 24), machinery accidents (31 to 50), and automobile accidents (304 to 373).—U. S. Department of Commerce, Bureau of the Census. Provisional Summaries.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Mosquito Control on Water Supply Reservoirs—Mosquito control may be effected by clearing the edges of ponds or reservoirs to eliminate floatage, by varying the water level 6"—8" to strand larvae, by destroying the larvae with *gambusia affinis*, and by the use of mineral oil. The use of mineral oil is claimed to be unobjectionable to water users. It is generally used in the upper reaches of the pond or reservoir and remains on the surface, whereas intakes are usually below the water surface.—E. W. Constable, *Water Works Eng.*, 82, 1929. From papers of Water Pollution Research Board, England.

Some of the More Recent Aspects of Sewage Chlorination—The amount of chlorine to be added for the proper disinfection of sewage varies with conditions of sewage and temperature, but 0.2 p.p.m. should be present after 10–15 minutes. Solution feed is recommended in preference to direct feed apparatus, since, when over 3.5 p.p.m. of gas are fed directly, damage to equipment may result from escaped gas. Chlorine may be added either to the plant influent or effluent. Direct feed apparatus may be used when an addition of not over 3 p.p.m. of chlorine is required. Disintegration of concrete, often due to the presence of hydrogen sulphide, may be prevented by chlorination.

Prechlorination is claimed to have no harmful effects on sludge digestion, but rather to hasten it, prevent foaming in Imhoff tanks, and reduce the 5-day biochemical oxygen demand of sprinkling filter effluents. The construction of secondary treatment facilities may be

postponed or avoided by chlorinating the effluent from settling tanks.—L. H. Enslow and J. A. Strange, *Fourth Annual Report of the Missouri Water and Sewerage Conference* from Papers of Water Pollution Research Board, England.

Engines Run on Sewage Gas—At the sewage works of Charlotte, N. C., gas is collected which contains about 70 per cent of methane, averages about 800 B.t.u. per cu. ft. in calorific value, and amounts to about 0.3 cu. ft. per head of the population per day. The gas is utilized in internal combustion engines and the heated water from the jackets is used, supplemented in cold weather by exhaust gas heaters, to maintain the required temperature in the sludge digestion tanks. A 10 per cent reduction in operating expense has been effected by the use of the gas.—*Power*, 69, 1929. From papers of Water Pollution Research Board, England.

The Treatment of Water and Waste Water with Chlorine and Copper and Chlorine and Silver—An apparatus is described and illustrated for the simultaneous addition to water of chlorine and copper or silver. Chlorine gas passes from a cylinder through a control system to a vessel where it is dissolved in a small quantity of water. The solution can be divided as required, part passing directly to the water to be treated, while part passes through another vessel containing silver and copper waste, carrying some of this in solution to the water.

Experiments are described on the

treatment with chlorine and copper of the water for use in a cellulose factory and the effluent from a paper factory. In the first case the water was drawn from a river so much polluted with trade wastes that neither chlorine nor copper sulphate sufficed to control growths of fungi and algae.

Combined treatment with 2.5 gm. of chlorine and 0.18 gm. of copper per cm. of water was entirely successful. Intermittent treatment of the clarified effluent from a paper factory was successful in preventing growths in a stream. The chlorine and silver combination was tested in river water with a very high content of bacteria and suspended matter.

Tests were made of the raw water and of the water after chlorine alone and silver and chlorine had been added on the suction side of the pump drawing from a well. The results of the bacterial counts and the coli-titer are given in tables. At first the quantities of silver were too small to increase the effect of the chlorine, but on raising the quantity of silver or adding ammonia the chlorine effect was increased.

The amount of suspended matter caused slowness in the action, but when the water was filtered sterilization took place much more quickly.—G. Ornstein and R. Kroke, *Gesund-Ing.*, 53, 1930. From papers of Water Pollution Research Board, England.

Pollution of Abandoned Well Causes Fond du Lac Typhoid Epidemic—An account is given of the report of Warrick and Tully on the cause of the typhoid outbreak at Fond du Lac, Wis., in 1929. The water supply is drawn from wells, five of which are situated at the water works. Bacterial examinations proved these wells to be polluted.

Information was received of the existence of an abandoned private well in a new channel of the Fond du Lac

River, some 800 ft. from the wells. The river receives tannery waste and sewage. Salt tests gave evidence of underground connection between this well and the wells at the works.

The old well casing was treated with chloride of lime and air tests were made for seams in the river channel. The old well was then filled with concrete and capped, the reservoir was cleaned and disinfected and the water mains flushed.

The discharge from the water works wells improved immediately the old well was capped, but all city water is now chlorinated and private wells in the neighborhood are carefully tested and controlled.—*Eng. News-Rec.*, 104, 1930. From Papers of Water Pollution Research Board, England.

Bacterial Contamination of Baths—Examinations of samples of water from swimming pools which are not subjected to filtration or chemical treatment, and from those which are treated by continuous filtration and chlorination, have shown that *B. coli* multiply rapidly during the night in swimming baths, but streptococci do not. It is suggested that a better index of pollution is formed by an estimation of streptococci by glucose and lactose broth than by an estimation of *B. coli*. It is concluded that while the *B. coli* content is not a universally reliable index of intestinal pollution, streptococci are constant indications of such pollution, and that although *B. coli* do not necessarily indicate pollution or danger, their absence is an excellent index of safety.—*Brit. M. J.*, 3593, 1929. From papers of Water Pollution Research Board, England.

Treatment of Dairy Wastes—The strength of milk-product waste depends primarily upon the buttermilk and whey content and may be 10 times the average for domestic sewage. The treatment of weak and concentrated dairy waste

is discussed. Reference is made to previous investigations which have shown that Imhoff tanks are unsatisfactory but that a purification of 80-98 per cent, based upon the organic nitrogen, is effected by septic tanks with 24-72 hours' detention, followed by sand or trickling filters. Concentrated wastes can be recovered, utilized as hog food, or dried.

Experiments were carried out on the chemical treatment of concentrated wastes at two New York State plants; 0.5-1.0 per cent of 95 per cent lime by weight was added to the raw waste, which had an acidity ranging from 1,000-6,500 p.p.m.

The sludge dried readily on sludge beds to about 46 per cent moisture and the clarified effluent showed a reduction of 86 per cent in organic nitrogen and 82 per cent in oxygen consumed.—C. L. Walker, *New York State Sewage Works Assn.*, Oct., 1929. From papers of Water Pollution Research Board, England.

Water Supply and Sewerage of Large Japanese Cities—The author gives an account of the water supplies, sewerage systems and sewage treatment works of the large cities of Japan. Water works methods are up to date and a high standard of water is generally supplied. Surface water treated by slow sand filtration is most usual, but rapid sand filtration is being introduced.

Sewerage systems have reached a high degree of development though the sewage in most cases is discharged without treatment. One full-size activated sludge plant is almost completed at Nagoya and the process is being tried on an experimental scale at other places.—H. E. Babbitt, *Eng. News-Rec.*, 104, 1920. From papers of Water Pollution Research Board, England.

Flat Clarification Tanks with Sludge Scrapers—Flat settling tanks

with mechanical arrangements for frequent removal of sludge during operation are being generally installed in Germany. Three forms of scraper are described: (1) a continuous chain scraper used in a narrow rectangular tank to push the sludge against the sewage stream to a sludge reservoir at the inlet end; (2) a scraper carried on a traveling bridge, also used in a narrow tank to push the sludge to the inlet end; (3) rotary scrapers for large tanks either square or circular, moving the sludge to a central collecting tank. For this purpose circular tanks with central inlets are most efficient and economical.

Rectangular tanks necessitate a complicated construction of scraper to reach the corners. Central inlets have the advantages of slower average flow for the same retention time and settling of the heaviest sludge near the sludge chamber. Even distribution of incoming sewage is of great importance. This can be achieved by surrounding the inlet with a circular screen of triangular wooden laths with their apexes outwards.

A detailed illustrated description is given of a circular clarification tank, 30 m. in diameter, with a rotary sludge scraper, at Essen-Nord, which treats sewage containing at times very large quantities of light watery sludge, due to iron pickling and chemical wastes. The sewage enters through a wooden lath screen and heavy solids are at once deposited in the sludge tank, lighter matter being carried over to the clarification tank proper.

Owing to the danger of earth movements due to mining, the sludge scraper is carried on floating pontoon bridges and the junctions of the actual scraping parts are all flexible so that they can accommodate themselves to unevenness in the tank floor. Scum is moved by hand into a channel carried by the scraper floats, and deposited in the sludge collecting tank. The sludge at the bottom of the collecting tank is

forced up pipes by the pressure of the water and deposited in a tank above the collecting tanks. By this means a sludge with a water content of 88-90 per cent is obtained.

Plans are described for a larger tank of this type, 45 m. in diameter. As a single sludge scraper of this length would have too slow a movement in the center, the tank is to be divided into an inner and an outer circle, and the small quantity of light sludge deposited in the outer circle will be moved, by a separate scraper running on rails, to sludge tanks under this outer tank, from which it will flow to the central collecting tank. This will also have the advantage that any sludge stirred up by a too rapid movement of the inner scraper will settle and be removed in the outer circle.—M. Pruss, *Gesund. Ing.*, 53, 1930. From papers of Water Pollution Research Board, England.

Chlorinated Drinking Water: The Use of Activated Charcoal Filters—The only drawback in connection with the chlorination of water is that of taste production. In the presence of the most minute traces of phenols, chlorine produces an objectionable taste and odor in the water.

The simplest control, elimination of the phenols, is practically impossible due to their varied sources. Furthermore, due to this variation it is impossible to control them from the sewage treatment side. The logical control is at the water purification plant. The process giving the best results, thus far, is filtration of the water through activated charcoal.

An experimental plant of 25,000 cu. m. daily capacity was installed by the

Ruhrverband. This plant has been in use for several months and has given good results in removal of chlorophenol tastes as well as tastes caused by algae and mineral constituents. This experimental charcoal filter is described in detail.—Karl Imhoff and F. Sierp, *Surveyor*, 76, 1963: 225 (Sept. 6), 1929. From *Pub. Health Eng. Abstr.*, Mar. 29, 1930. Abstr. F. E. DeMartini.

The New Refuse Disposal Plant, Chapman Street—At the new 120 ton refuse disposal plant which replaces the old destructor, everything of value is salvaged and only valueless refuse burned. The refuse is tipped from the collecting vehicles into a hopper and is carried by a continuous plate conveyor to an elevator which lifts it to the long rotary screen. This has a 12 ft. section with 5/16 inch perforations which pass small particles, and 6 ft. of 1½ inch holes through which fall principally cinders. The brass extension to the screen has electro-magnetic coils on one side which separate out the tin cans, which are then chuted to the baling press.

The remainder of the refuse is conveyed on a rubber belt to the firing floor of the incinerator, and paper, glass, bones, etc., are hand picked off the belt. The tailings are burned in a specially designed incinerator to heat steam boilers which drive dynamos that generate the current for the plant and an excess which is sold.

The plant also includes a paper baling press, a clinker crusher, and a mortar mill.—Anon., *Health News*, Hull Corporation, England, 2, 12: 1-2 (Sept.), 1929. From *Pub. Health Service Eng. Abstr.*, Mar. 1, 1930. Abstr. A. W. Fuchs.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., AND LEONARD GREENBURG, PH. D.

Pocket Reference of Information on Occupations—This little booklet, prepared by the U. S. Bureau of the Census chiefly for undertakers and registrars of vital statistics, explains the new requirements which relate to occupations and the census of occupations made in 1930.

The new death certificate which has been introduced in the past year or so is to be the one used from 1930 on, in the entire death registration area, which now composes 95.8 per cent of the population of the United States. The headings which refer specifically to occupations are as follows:

Trade, profession or particular kind of work done, as spinner, lawyer, bookkeeper, etc.

Industry or business in which work was done, as silk mill, saw mill, bank, etc.

Date (month and year) deceased last worked at this occupation. Total time in years spent in this occupation.

A study of death rates by occupation, such as that planned in connection with the 1930 census, would not be limited to those deaths directly traceable to occupational activities; it would go considerably further, and be perhaps comparable to the report to the British Registrar-General, issued for England and Wales. It is realized that adequate reports on occupations will influence insurance rates, workmen's compensation laws, industrial hygiene activities, and the changes brought about in industry by employers, while it would, of course, make it possible to compare the death rate of workers by occupations and by localities.

While the undertaker is responsible for filling out the blank originally, the local registrar is to review the occupa-

tional returns and refer them back where not completed or where the facts are known to be otherwise than stated.

The pamphlet contains a list of instructions to enumerators who took the 1930 census in reference to the questions above, which will be of assistance to those who fill out the death certificates. There is an extensive list of undesirable terms which are to be avoided, and the reasons therefor.

In preparation of the booklet, the valuable services of the National Tuberculosis Association were used, while the revised standard certificate of death was approved at the meeting of the A. P. H. A. in Chicago, October, 1928, and by the conference of State and Provincial Health Authorities, in Washington, in June, 1929.—E. R. H.

Anthraxis—This disease is differentiated from emphysema by the absence of a deformed thorax and alteration of the general condition. Gray sputum is more common than black sputum usually mentioned. Physical signs do not indicate pulmonary induration.

The radiologic signs indispensable for a diagnosis are bilateral lesions at the base and around the hilus, disseminated and nodular at first, but later confluent and encircled by an area of emphysema.

Silica is not a common substance found in coal mines, yet sclerosis among miners is frequent. Nor are bronchitis and emphysema essential factors of sclerosis.—Belgium Letter, *J. A. M. A.*, 95, 10: 741 (Sept. 6), 1930.—E. R. H.

Asbestosis Bodies in Sputum and Lung—While the asbestos industry is more than 2,000 years old, it is only

within the past few years that it has assumed the prominent place which it now occupies in the industrial arts. Until recently asbestosis has been assumed to be essentially silicosis, and the free silica thought to constitute the dangerous factor. (A brief review of bibliography on the subject is made, beginning with the article in 1924 by W. E. Cooke in the *British Medical Journal*, July, 1926.)

In October, 1929, the present authors autopsied a negro patient, dead of a gun shot wound, who had worked for 28 months during a period of about 3 years in an asbestos mill (Charleston, S. C.). Microscopic examination of lung tissues, peculiar bodies were found in sections from both lungs, which are considered characteristic (two illustrations accompany). At about the same time another autopsy was performed on a negro who also died of lobar pneumonia and who had been working in an asbestos mill for $4\frac{1}{2}$ years. Again the "asbestosis" bodies were found on microscopic examination of the lung sections. Following this, search was made for the bodies in the sputum of asbestos workers, where they were readily found in wet slide preparations and in large numbers in a sodium hydroxide digest concentrate.

Examination of a man who had worked 14 years in an asbestos factory, but not since 1926, failed to reveal the bodies. It was found the bodies do not take the ordinary tissue and sputum dyes but may be found in their natural form in slide preparations already stained for the tubercle bacilli. An unexplained iron content of the bodies was also brought out by certain stains.—K. M. Lynch and W. A. Smith, *J. A. M. A.*, 95, 9: 659-661 (Aug. 30), 1930.—E. R. H.

The Occurrence of Pulmonary Fibrosis and Other Pulmonary Affections in Asbestos Workers—This very interesting contribution presents

the results of a study of the health hazard among asbestos workers. In addition to the presentation of clinical data and X-ray pictures the morbid anatomy of the disease and dust findings in the industry are clearly set forth.

It is pointed out that asbestosis differs from ordinary silicosis both in the gross morbid pathology and X-ray examination. For this reason it is correctly argued that X-ray pictures of the chest of asbestos workers must not be interpreted in terms of the X-ray picture of the worker in other dusty trades.

As in the case of other dusts the end result varies directly as the length of employment and the dust concentration. With high concentrations the disease may be developed in from 7 to 9 years and may cause death in 13 years. The author concludes that further investigation is required in order to decide whether or not there is any increased susceptibility to pulmonary tuberculosis due to the inhalation of asbestos dust or the presence of asbestos fibrosis.—E. R. A. Merewether, *J. Indus. Hyg.*, 12: 198-222, 239-257 (May and June), 1930.—L. G.

Health Service Policies—This is *Health Practices Pamphlet No. 12*, published by National Safety Council, 20 N. Wacker Drive, Chicago, Ill., and includes a study of prevailing practices based upon answers received from 191 clients, companies and their physicians. The personnel of the various plants is analyzed by groups and the types of service rendered—preventive, curative, and related activities—are classified. A composite picture gives the average features respecting industrial medical services in these plants (20 items, too long to enumerate in this place).

It was found that only 5.3 per cent of 3,580 selected industrials reported on some form of medical and health supervision of their employees. Thus, approximately 3,406,000 employees were

not reported upon as compared with 1,615,193 who were, as having health service provisions.

The minimum requirements for a health service are summarized as follows:

1. Pre-employment physical examinations
2. Treatment for minor illnesses
3. The service of a part-time physician
4. The service of a full-time dispensary nurse

The maximum requirements compose a discussion of 13 items, given in some detail.—E. R. H.

Studies in Illumination. III—A Study of the Loss of Light Due to Smoke on Manhattan Island, New York City, During the Year 1927, Especially in Its Relation to the Nature of the Weather, the Relative Humidity of the Air, and the Velocity and Direction of the Wind.

For this purpose, records were made on the roof of the U. S. Marine Hospital, at the lower end of Manhattan Island, where the air was unusually smoky, and on the roof of the U. S. Quarantine Station on Hoffman Island, about 9 miles distant in lower New York Bay, where the air was comparatively clear.

Determinations were made with a photo-electric cell connected to a recording potentiometer. The photo-electric cell had been previously calibrated with a Macbeth illuminometer. It was only necessary to multiply the reading of the tracing stylus by 177 to obtain results in approximate foot-candles. In general, agreement was found with Kimball's contention that illumination is approximately proportional to the total radiation. The records were made during the year 1927, over a period of 286 days.

The highest average daily illumination at Hoffman Island occurred in June and the lowest in December. The greatest total loss of light on lower Manhat-

tan was in July and the least loss was in December. There was a large relative loss of light due to smoke—in some cases greater than 50 per cent.

The average percentage loss of light for the whole year was 16.6 for clear days, 34.6 for cloudy days, and 21.5 for all days. The percentage loss on cloudy days was about twice as great as on clear days.

The average percentage loss throughout the year was 30.2 at 8:30 a.m., 16.5 at 1:30 p.m., and 21.0 at 3:30 p.m.

The average monthly percentage losses showed no marked seasonal effect but did show a marked relation to the average monthly relative humidities, the percentage losses usually increasing and decreasing with the relative humidities.

Other conditions being the same, the percentage loss of light was found to decrease as the velocity of the wind increased.—James E. Ives, *Pub. Health Bull. No. 197*, 40 pp., 1930.—E. R. H.

Occupation and Health—The brochures which have been received under this heading from Nos. 206–212, inclusive, are as follows:

- No. 206, Flour Mills
- 207, Garages
- 208, Industrial Health (Propaganda)
- 209, House Porters
- 210, Industrial Lighting
- 211, Industrial Physiology
- 212, Jute

As stated in the September issue, brochures in this *Encyclopedia of Hygiene, Pathology and Social Welfare, Studied from the Point of View of Labour, Industry, and Trades* are said to be now completed through the letter "E" (Brochure No. 199). The price of the complete Brochure Edition is \$16.00 and may be purchased through the Book Service, American Public Health Association. The work is prepared by special committees under the auspices of the International Labour Office, Geneva, Switzerland.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

The Williams-Waterman Vitamin B₃—This experiment was undertaken to supply information on the vitamin B₃ factor described by Williams and Waterman in the case of pigeons in contradistinction to the vitamin B₃ factor reported by Reader in the case of rats. The relative potency in certain foods in the vitamin B₃ factor was determined by feeding adult pigeons a synthetic diet adequate except for vitamin B complex, until symptoms of polyneuritis appeared, when an adequate amount of the vitamin B₁ factor was added.

The food to be tested was supplied and effect on growth and weight noted. These tables show beef liver and lean beef to be superior in the B₃ factor to milk, fruit and vegetable juices. Where the food was also deficient in B₁ weight restoration did not take place, showing this factor as well as B₃ to be essential in this respect. Vitamin B₃ factor in yeast is reduced markedly with alkaline treatment and in malt extract by heat.

Autoclaved yeast had no effect on weight restoration, showing this also not a property of B₂. The authors have been unable to show the need for vitamin B₃ in rats but an experiment with Rhode Island Red chicks indicated in these birds that B₃ is an essential for growth. In this experiment autoclaved feed, with B₁ and B₂ supplements, did not restore growth although protecting from polyneuritis.—Walter H. Eddy, Samuel Gurin, and John Keresztesy, *J. Biol. Chem.*, 87: 729 (July), 1930.

Vitamin G in Certain Meats and Meat By-Products—Vitamin G (B₂) is reported as occurring in varying amount in beef and beef liver and the

authors have previously found in commercial beef extract a good source of this vitamin. In this experiment rats were fed a ration containing corn extract for the vitamin B₁ but lacking G (or B₂) until growth ceased, when the meat and meat by-products were added. These were trimmed free from fat and connecting tissue and dried at 60° C. with forced draft and where fat was present extracted with ether.

Supplementary material included beef (round steak), pork tenderloin, smoked ham, lamb, beef liver, pork liver, beef kidney, and beef spleen. Twenty-five per cent of the basal ration in beef furnished sufficient vitamin G for good growth. Pork tenderloin and smoked ham compared favorably with beef; 15 per cent of the former and 20 per cent of the latter resulted in excellent growth. Fifteen per cent of lamb was adequate for good growth. Fifteen per cent of spleen supplied sufficient vitamin G for good growth.

Both beef and pork liver and beef kidney are much richer in vitamin G than lean meat. Good to excellent growth resulted from 1.38 to 3.05 per cent additions of these products. All comparisons were made on the basis of air-dried fat-free material.—Ralph Hoagland and George G. Snider, *J. Agri. Res.*, 41: 205 (Aug. 1), 1930.

A Method of Purification of Carotene and the Vitamin Activity of Purified Carotene—Many recent investigations in the literature on the activity of carotene prepared from leaves or carrots indicate that the substance was not especially purified although Drummond has claimed that purified

carotene, melting point 185° , possesses no vitamin activity, contrary to the views of von Euler and Karrer.

Attempts were made to purify carotene without altering its physiological properties and assuring a separation from the impurities which accompany this presumably inactive carotene. Carotene was prepared by solution in carbon disulfide, crystallization in boiling methanol in an atmosphere of nitrogen. There was obtained crystallized carotene from carrots, melting point 170° to 173° , and showing biological activity on rats in daily doses of 0.03 mg. Five additional purifications resulted in a product, melting point 184° to 185° , which the authors regard as a very high degree of purification.

This product was found active as to vitamin A; a dose of 0.06 mg. per day stopped the loss of weight, cured xerophthalmia, and resulted in increased growth, a daily gain of about 1 gm.; 0.045 mg. gave approximate results; 0.03 mg. stopped the loss in weight and cured xerophthalmia but the resumption of growth in the animals was not uniform. Some of them merely maintained their weight. This product, which is found to be physiologically active, had the same melting point as that reported by Drummond for carotene as inactive.—M. Javillier and L. Emerique, *Compt. rend. Acad. d. sc.*, 191: 226 (July 28), 1930.

Bacterial Spoilage of a Thousand Island Dressing—The spoiled dressing which was studied was composed of a mayonnaise base made from corn oil, vinegar, egg yolk, sugar, paprika, mustard and pepper to which were added pickles, olives, and chili sauce. The pH of the product was between 4.2 and 4.4.

The spoiled material was darker in color and showed separation of oil in varying degree. Spoilage was found to be due to growth in the dressing of a pure culture of an organism closely resembling *B. vulgatus* (Trevisan).

After examination of the chili sauce and egg material used showed that these ingredients were not the source of the contamination, attention was given to the salt, sugar, vinegar, mustard, pepper and paprika. Organisms identical with that causing the spoilage of the dressing were isolated from the pepper and paprika. The mustard also contained a closely related species of spore forming organism. The other ingredients contained no bacteria similar to *B. vulgatus*. It is suggested that this type of spoilage may be prevented by: (a) preparing a product of such acidity that it will not allow the growth of organisms, or (b) sterilization of the ingredient which contains the contaminating organism.—Carl S. Pederson, *J. Bact.*, 20: 99 (Aug.), 1930.

Nutritional Potency of Fresh, Cooked, Dry and Alcohol-Extracted Liver—The literature has emphasized the importance from a nutritional standpoint of calf and cod livers; so experiments were undertaken to determine the nutritional value of other livers and whether this value would be retained on drying, so as to make a prospect for an available supply over long periods in view of the increasing cost of calf liver.

Livers were obtained from calf, steer, lamb, pig, hog, colt, horse, chicken, rat and cod; they were comminuted and dried at 100° C. and the dry material ground in a mill and placed in air-tight containers.

A synthetic diet was prepared essential in nutrients and mineral salts but lacking in the accessory vitamin factors. Rats lost 1 gm. per day on this synthetic ration and after 17 days supplements of the dried liver were fed for 10 days. The supplement was 4 gm., equivalent to 16 gm. of fresh liver. Rats on the synthetic ration alone and on this supplemented by raw beef liver served as controls. Growth curves show that in no case did dried liver addition result

in gains over the synthetic diet alone.

When the supplement was changed to raw liver and cooked liver rapid gain was made. Less rapid gains were made with alcohol extracted raw liver, showing that some accessory is lost in the extraction. Supplements of raw tomato and potato resulted in fair gains but no gain when these vegetables were cooked. Analyses of the livers of different animals show a number of variations. Copper in the calf, lamb and steer livers is approximately 10 times that in the hog, pig, horse, chicken, rat and cod. Iron in the colt, horse, pig and hog livers is approximately 3 times that in other domestic animals. The chicken liver has 4 times the amount of fat of any other liver. Apparently, calf, lamb, steer and chicken livers are on a par as to mineral and nitrogen and on this basis similar nutritional values might be expected to compare with calf liver.

This experiment indicates conclusively the loss of valuable accessories on heating and drying in air at 100° C.—J. S. McHargue, W. R. Roy, and F. E. Hull, *J. Nutrition*, 3: 49 (July), 1930.

Vitamins in Canned Foods. IX. Tomato Products—Various tomato products were fed to rats and guinea pigs to determine their potency in vitamins A, B, and C. The canned products used were whole tomatoes, cyclone juice heated to 140° F. under vacuum, similar juice concentrated to a pulp condition and further concentrated to paste, cyclone juice to which Celite was added and then filtered free of unsoluble pulp, plain cyclone juice held 1½ hours before canning, similar juice evaporated for 45 minutes in wooden tubs, cold tomato juice obtained during the peel-

ing process and juice obtained after steaming the tomatoes.

If the various products are fed on equivalent solid levels their vitamin A potency is approximately similar with the exception of the cyclone juice to which Celite was added and which was then filtered. The vitamin A is removed with the pulp by filtering. The vitamin B content of tomatoes is somewhat affected by certain processes wherein excessive exposure to oxygen occurs. Filtering with Celite reduced the vitamin B potency of the tomato juice by about two-thirds. Vitamin C in tomatoes is apparently quite stable to heat if oxidation is avoided.

In none of the products studied was the vitamin C conserved as in the regularly sound whole tomatoes. In concentrated products such as pulp and paste there was some loss of vitamin C. This was not due to concentration but was brought about before evaporation due to oxidation because of air entrapped in the juice during its passage through the cyclone. Concentration under vacuum corrects this condition and prevents further loss.

Rapidly heating cyclone juice to boiling and concentrating to two-fifths of its volume in an open kettle by boiling for 45 minutes does not permit the entrapped air to exert a destruction of half the vitamin C. Damaging air will not be beaten into tomato juice if cycloning is done while the juice is hot.

Data are given to show how steam may be employed to avoid contact with air in a manner which may have wide application in the handling of foods.—E. F. Kohman, W. H. Eddy, and C. Zall, *J. Ind. & Eng. Chem.*, 22: 1015 (Sept.), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

Well Guided Experience Is One of the Prime Requisites for Progress in the Public Health Nursing Profession—Probably every public health nursing executive, and certainly every state director of public health nursing, finds that she is now and then consulted by a staff nurse or a nurse out in the field as to how she can rise a step higher in her profession. Some of these nurses consulting her have stayed in one position for years, perhaps with a little increase in salary each year, or they have shifted from one school nursing or one county nursing position to another. They feel that that they ought to grow, to advance, to take added responsibility. We need many of these nurses who are content to stay on and do the great bulk of public health nursing; yet there are others who are unhappy and not doing their best work standing on a level year after year. They are ambitious and usually have vision and executive ability; our leaders in public health nursing must be recruited from these.

What advice do we give them? If they want to be the executive directors of public health nursing associations, no better advice can be given than that embodied in *The Board Members' Manual*:

The generally accepted standard for large associations is that she should be a high school graduate, a registered nurse graduated from an accredited school of nursing, preferably have had postgraduate work in public health nursing at some accredited college, experience as staff member of a public health nursing organization giving adequate supervision, experience as a supervisor, and, when possible, as an

assistant executive director. She should have sound administrative ability to organize and direct the work.

That nurse is lucky who during her nursing training had two or three months' field work with a good public health nursing organization, for this extra experience, though only giving her an inkling of what public health nursing is, enables her more easily to get a staff position with the organization after finishing training, provided her record is good and her personality suitable. Then after she has completed one, two, or three years of staff work, what if she wishes to go into another phase of public health nursing? The next step is to take one of the accredited university courses in public health nursing for 4 months—or better, 8 months. This will broaden her outlook on all phases of public health nursing, and she is then able to take a public health nursing position alone. If she makes good in a position by herself with her staff training and theoretical course behind her, she is in line for a position of greater responsibility, and can then begin to climb.

But what of the nurse who, after finishing nursing school, went directly into a public health position where she worked alone without training or supervised experience? If she finds she has advanced as far as she can, the only thing for her to do is either to get a position on a good public health nursing staff which has a good staff education program or take a university public health nursing course, and it is better to do both if her goal is to be an executive in a generalized, or even a specialized, public health nursing program.

For instance, a nurse who had been

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

doing school nursing by herself in a small town 6 years, with courses in university during 3 summers, is now on a well organized visiting nurse association staff where her promotion will undoubtedly be rapid. Another, a staff nurse for a good public health nursing association for 6 years, and wishing to get a county nursing position, will take a 4 months' university course before she is recommended for a county position.

But what of the great number of nurses who are just out of training school or who have been doing private duty and who never had any public health nursing during training or after? Since some of the university courses only accept students who have had some public health nursing training, they are cut off there. Their only hope is to get a staff position first and then take their university course; and there are not staff positions enough to go around. But for these nurses to go out and take public health nursing positions, even if organizations would employ them, is an injustice to themselves and to the communities.

It would seem that in order to train public health nurses better there needs to be more staff positions open to them. And this would be possible if more official agencies would employ real public health nurses as their supervisors or executive directors, so there could be a staff education program. The nurses on some official staffs are getting unguided experience. A physician or health officer cannot train nurses in their work; otherwise, why are physicians not superintendents and supervisors of nursing schools? There are some official agencies in the country, both city and county, which do employ well trained nurses as their directors, and they are accomplishing the outstanding work that is being done.

But what if a nurse has had all the experience and training that are necessary to direct a public health nursing

staff, either small or large, and she does not advance or get anything like the kind of position she wants? Then she had better study herself and see if her personality stands in her way—for as Malinde I. Havey, R.N., of the American Red Cross said after a study of nursing qualifications for rural nursing, "A course will do without experience; good experience will do without a course. But of the three things, theory, practice, personality, the greatest of these is personality."

New School of Nursing at Vanderbilt University—The School of Nursing at Vanderbilt University at Nashville, Tenn., has been organized as an independent school of university rank through the financial support of the Rockefeller Foundation. The school will offer not only programs of study to undergraduate students, but to graduate nurses as well.

Shirley C. Titus is Professor of Nursing Education and Dean of the School of Nursing at Vanderbilt University. Miss Titus is well known in the nursing field of this country. She holds a B.S. from Teachers College, Columbia University, and an M.A. from the University of Michigan.

Beginning September, 1930, courses will be offered to graduate nurses in public health nursing. The public health nurse may matriculate for a 4-year course leading to a B.S. degree; she may register for the 9 months' course, the satisfactory completion of which entitles her to a certificate in public health nursing; or she may take the 6 weeks' extension course which will be offered each summer (on or about June 12).

Mary J. Dunn is Professor of Public Health Nursing in this new school and will organize and direct the courses in public health nursing. Miss Dunn holds a B.S. from Teachers' College, Columbia University, and has had a varied experience as assistant consultant in

maternity, infancy and child hygiene with the New York State Department of Health—later with Cornell University as instructor in child care and training. For the past two years she has been educational director of the Bureau of Nursing, New York City Department of Health, and part-time instructor at Columbia University.

With its own dean, faculty and budget the Vanderbilt School of Nursing represents one of the most complete teaching centers for nursing education in the United States.—From announcement sent by Vanderbilt University to the A. P. H. A.

The Nurse the Doctor Wants—
The ideal nurse for the present-day physician is one who has good breeding and an attractive personality, skill in giving general care and making patients comfortable, who can observe and report symptoms well, takes care to follow medical orders and is adept at handling people.

This picture of the perfect nurse was ascertained from questionnaires sent to doctors in many branches of medicine, by the Committee on the Grading of Nursing Schools, which is conducting a 5-year study of nursing and its problems. The above qualifications were the five most stressed by the more than 4,000 physicians from all parts of the country who answered the queries.

Just how the various requirements for a good nurse rank in the minds of the physicians as a whole may be seen from the following:

Requirements	Per cent
Skill in general care	65
Skill in making the patient comfortable	65
Skill in observing and reporting symptoms	45
Care in following medical orders	43
Good breeding and attractive personality	34
Skill in handling people	30
Skill in asepsis	28
Familiarity with hospital routine	27
Experience and background	22
Familiarity with their personal methods	21

Ability to work under a heavy strain	15
Familiarity with a particular disease	15
Responsible adult to take charge of the family	3
Mother's helper and houseworker	3

The modern physician thus places the old-fashioned concept of a nurse as "a pair of hands and feet" at the bottom of the list. His demand now is for a woman of good background, of high professional principles, with thorough training and experience in the actual care of the patient, as nurse for his cases.

The study shows that the demand for practical nurses by physicians is steadily dropping, with 84 per cent preferring the graduate, registered, trained nurse at all times for their own cases, and an additional 8 per cent preferring them always for certain types of cases.

The general practitioner and the internist are most interested in the ability of the nurse to give general care, 69 per cent and 70 per cent, respectively, registering for this quality, as compared with the average percentage of 65. The neurologist is least interested in it, though more than half of those questioned checked for it.

Skill in observing symptoms is most desired from the nurse by the surgeon, neurologist, obstetrician and pediatrician. The three last-named groups also had a more than average interest in the qualification of good breeding and personality. The surgeons emphasized skill in asepsis and care in following medical orders as well.

The neurologists are by far the most interested in having for their patients nurses who can handle people, 61 per cent checking this, as compared with an average of 30 per cent.

Nurses who take particular care to follow orders shine brightest in the eyes of the pediatricians, 57 per cent of them desiring this qualification, while the average demand is 43 per cent. The surgeons and the obstetricians are most interested in having nurses familiar with

hospital routine and their personal methods.

Nine out of 10 physicians reported they are getting the nurses they want and would be glad to take the nurse on their last case back again. The surgeons were the group most satisfied, 63 per cent of them marking their nurses with the highest rating.

Some of the typical comments made by the physicians, that show what they appreciate in nursing care specifically, were:

A good observer, gentle, thorough. She follows orders explicitly and reports changes promptly.

My nurse has a sense of humor, which helps a lot.

She kept hordes of anxious relatives and friends out of the room.

She has always been cheerful.

She combined a good technical training with common sense.

She carried out orders but modified them when the need was obvious.

She had a proper sense of the dignity of the position.

She is intelligent, observing, not afraid to take a severe case twelve miles in the country.

She was a good cook and knew how to handle people.

There has been a very distinct improvement in the patient's mental condition during her stay in the hospital.

Her asepsis was perfect.

She was of great value in preventing a psychosis from developing.

One of the nurses was exceptionally good-natured and tolerant.

Anyone who can feed a patient a half-pound of cooked liver daily for 4 or 5 months deserves credit for being a good cook and knowing how to handle people.

She sees to it that even the family are happy.—

Nurses, Patients and Pocket-books, 1928, p. 121; *Nurses: Production, Education, Distribution, and Pay*, May, 1930, 36 pp. Bull. Committee on the Grading of Nursing Schools, 370 Seventh Avenue, New York, N. Y.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

We Are Being Studied and Written Up—1930 will be notable for special recognition of health education by research workers and writers of reference works. An extensive study of health education in a large city has been published. A book manuscript reporting on health education through a period of years in a city is under consideration. Health education, both popular and in the schools, will be reviewed in the *Social Work Year Book* about to be issued by the Russell Sage Foundation. An encyclopedia article on popular health education is in manuscript form.

A study of education in mental hygiene has just been completed. Another study in the mental hygiene field has been announced. A careful review of social hygiene educational material recently made has been utilized in the planning of several experimental campaigns. A university thesis has been based upon an examination of public health in newspapers. A study of health education results in a county has included an examination of the newspapers upon which a university thesis will be built. The city health surveys have included small chapters on health education. And of course 1930 has seen much and varied study and formal discussion of the teaching of health in schools and colleges.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

We Thank the Guest Editor—If in the fall rush you missed this department in the September and October issues of the JOURNAL, look them up and you will know why we thank Dr. H. E. Kleinschmidt of the National Tuberculosis Association.

Syndicated Health Information—The "Annual Directory of Features" shows that "health advice columns were never more abundant." Twenty columns are listed by *Editor and Publisher* (Times Bldg., New York Aug. 30, 1930), the authors including Drs. Morris Fishbein, G. Logan Clendenning, William Brady, George C. Tallerday, Sophia Brunson, Royal S. Copeland, W. A. Evans, Iago Galdston, Frank McCoy, Joseph Jastrow, James W. Barton, John Joseph Gaines, Clarence W. Lieb, Leland B. Alford, and G. Leroy Dale. In contrast it is interesting to note that 109 sport page features are distributed. The directory includes lists of writers and artists, feature and picture syndicates, news, photographic, mat and art services.

"Unfortunate Advertising"—A warning from a professional journal seems to set a standard for all publications of all types in the public health field—and for the more or less educational printed matter from commercial sources so frequently distributed by health agencies:

Complaints are beginning to be heard regarding the advertising policy of some of our professional journals. There is a growing feeling that some of the advertising is detrimental to the best interests of the profession, and serves to hinder the proper development of . . . by placing around unworthy and unscientific preparations an aura of respectability that they by no means deserve. Forward-looking practitioners appreciate that honest and well directed advertising is a valuable means of informing the profession of products worthy of their attention. But they also are aware that intrinsically dishonest advertising, either by advertising scientifically worthless

preparations or by misstatement of fact, is a perversion of editorial license, and a disgrace to any profession which tolerates it.

There is enough information available, both scientific and regulatory, to make possible an honest and judicious selection of products for advertisement and the statements contained therein. The situation might be excused if there were no such information but since the publication of the exposes from the . . . conscientious practitioners may well question the motives and policies of those who carry such advertising. . . . In the long run, if any journal expects the support of the profession, it must prove its good faith by accepting only advertising that is honest.

DIPHTHERIA

A good 4-page folder to follow up a diphtheria campaign—Westchester Tuberculosis and Public Health Association, 8 Church Street, White Plains, N. Y. 2 cents.

The Board of Health, Racine, Wis., supplies a blue button with white letters reading: "I am Schicked—Are You?" Sample, 5 cents.

Buffalo department stores are using a 2-page leaflet, reproduced in *Health News*, State Department of Health, Albany, N. Y. June 23, 1930. Free.

"The Battle Against Diphtheria—News from the Front Line Trenches." *Public Health Nurse*. June, 1930. Reports from Bakersfield, Detroit, and elsewhere.

HONORABLE MENTION

To State of Ohio Department of Education: for bibliography in Health Education in Health and Physical Education Series—for dating most of the titles listed; names of publishers (and addresses of some of them); and prices of most pamphlets listed.

To Board of Health, East Orange, N. J.; Department of Health, Montclair, N. J.; Department of Health, Syracuse, N. Y.; Bureau of Public Health, New Mexico: for annual reports, all different, but all good—in the clear grouping of information, use of diagrams, table contents, and index (in two of them).

RADIO

Health broadcast number 370 was released Sept. 15, 1930, by the U. S. Public Health Service.

Mimeographed copies of radio talks by New York City Department of Health are available. *Free*.

Reports of radio addresses over WCCO are reported in the issues of *Everybody's Health*, St. Paul, Minn. 10 cents.

Mimeographed copies of five radio talks given over WEEI are supplied by Massachusetts Society for Mental Hygiene, 5 Joy St., Boston, Mass. *Free*.

The Connecticut State Department of Health has announced topics for 5-minute talks every Thursday, September through May, over WTAC. List *free*.

Printed copies are available of broadcasts by the National Safety Council, 20 North Wacker Drive, Chicago, Ill. *Free*. Given Friday evenings over 23 associated NBC stations.

Thursday, September 25, 1930, the New York State Department of Health broadcast its radio health talk number 432! Every Thursday from station WGY. The new releases on these radio talks show that nearly always the speakers cut out the opening generalizations and get down to business with the first sentence—due largely to the 5-minute limit.

MOTION PICTURES

For the cost of the negative, a college, school or local amateur movie club will produce a picture portraying health facts, ideas, or activities.

Camp Sanitation, "produced in collaboration with the Indiana State Board of Health," is offered by National Motion Pictures Co., Indianapolis. 1,000 feet.

A one-reel educational motion picture, showing sanitation in camps and rural districts where modern sanitary features are not always obtainable.

New Methods of Malaria Control,

"produced in collaboration with the U. S. Public Health Service, and under the supervision of J. A. LePrince and H. A. Johnson," is offered by Universal Cinema Co., Indianapolis, Ind. 1,000 feet. Both 35 mm. and 16 mm. film.

This film is crowded with workable methods so convincingly simple that these can be readily patterned after. Besides this, the appeal of this film is of such human interest and force that the public will rally to the cause and cooperate with the public health officers in their mosquito eradication work.

The 1930-1931 edition of Selected Motion Pictures lists 34 titles under "Safety, Sanitation, First Aid and Health." Pictures supplied free. Motion Picture Bureau, National Council, Y. M. C. A., 120 West 41st St., New York, N. Y. *Free*.

"Films in Teaching Anatomy," by H. W. MacMillan, D.D.S. *Movie Makers*, 105 West 40th St., New York, N. Y. Oct., 1930. 25 cents.

"How Animated Cartoons Are Made," by Quinn Martin. *N. Y. World Magazine*. Sept. 29, 1930.

"Nut Crackers," by D. C. McGiehan. *Movie Makers*. Oct., 1930. "Home made helps for ambitious amateurs." Also, "Let's Make a Title Board!" by I. H. Smith.

"The Movies in Medicine," by Carl D. Clarke. *Hygeia*. Sept., 1930.

DIPHTHERIA

A bull's eye diagram with 64 named dots represents the status of T. A. T. immunization of children under 5 years of age in as many communities in New York State. The idea could be applied to townships in a county or to wards in a city. In *Health News*, New York State Dept. of Health. Aug. 11, 1930.

A house-to-house canvass by nurses to interest parents in having their children immunized is described in *Weekly Health Review*, Dept. of Health, Detroit, Mich. Sept. 6, Sept. 20, 1930.

Governor Larson has been asked by

the New Jersey Committee for the Prevention of Diphtheria to grant it an honorable discharge. The committee feels that its work has been completed and suggests that further conduct of the campaign against diphtheria be carried on by the medical profession, health departments, and local groups organized by the state committee since it was appointed by Governor Moore three years ago.

EDUCATIONAL MATERIAL

Catalogue of Bureau of Dental Health Education, American Dental Assn., 58 East Washington St., Chicago, Ill. July 15, 1930. All forms of educational material. *Free*. Get copies for local groups interested in mouth hygiene. Thus you may help along with little effort and expense.

"Check List of Red Cross Publications." *Red Cross Courier*, Washington, D. C. Sept 2, 1930. *Free*. Some are useful to other agencies.

Public Health Service Publications. In *Public Health Reports*, Washington, D. C. Aug. 29, 1930. Titles issued 1929-1930—both popular and professional. Supt. of Documents, Washington, D. C. 5 cents.

Dr. Gerald B. Webb, Colorado Springs, Colo., is writing a pamphlet on "What You Should Know About Tuberculosis" for the National Tuberculosis Association.

The Care of Your Baby, by U. S. Public Health Service. Supt. of Documents, Washington, D. C. 50 pp. 10 cents.

Milk, by Agriculture Dept., Washington, D. C. 8 pp. 5 cents. Sanitation in production.

Social Hygiene in Relation to Prevention of Blindness, National Society for the Prevention of Blindness. 370 Seventh Ave., New York, N. Y. 32 pp. 25 cents. Get copies for editorial writers, and a few key individuals.

Watch Your Step! (feet); Attention!

Stand Tall! (posture); Care of the Child in Hot Weather; Supplies Necessary at Time of Confinement; Sensible Sun Baths. Massachusetts Dept. of Health. Samples *free*. Note how effective simple text and illustrations can be, and learn from your printer how antique paper would add but little to the cost with considerable gain in attractiveness.

The Home That is Safe (12 pp.); Helpful Suggestions About Infant Paralysis (4 pp.); Give Your Heart a Chance (12 pp.); What is Rheumatism? (12 pp.). Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y. *Free*.

Catalogue of Free Publications. Evaporated Milk Assn., 203 North Wabash Ave., Chicago, Ill. *Free*.

List of Free Publications. California Fruit Growers' Exchange, Los Angeles, Calif. *Free*.

NEW

The Journal of Cancer Research has become *The American Journal of Cancer*, 1145 Amsterdam Ave., New York, N. Y., with a broadening of its editorial range.

MAGAZINE ARTICLES

These articles contain much quotable material for writing and speaking. They reveal health teaching which reaches large numbers of readers. Sometimes they will suggest friendly letters of correction to editors.

As a rule we do not list articles in *Hygeia*, *The Survey*, or in professional magazines which are available to all public health workers.

"Are you a Heliophobe?" *Literary Digest*. Aug. 2, 1930. Page 26.

"Can We Extend the Life Span?" by Louis I. Dublin. *Harpers*. May, 1930. Page 766.

"Don't Blame the Stork," by Ruth F. Wadsworth, M.D. *Colliers*. Aug. 23, 1930. Sex-determination.

"Fewer Die; Fewer Born." *Literary Digest*. July 19, 1930. Page 12.

"Infantile Paralysis," by George Draper, M.D. *Harpers*. Feb., 1930.

"Let Your Doctor Do It!" by Logan Clendenning, M.D. *Colliers*. Aug 2, 1930. The "specialist" in "general practice."

"New Wasp to Fight Mosquitoes." *Literary Digest*. July 19, 1930. Page 27.

"Rat Pie," by C. C. Van Blarcom. *Harpers*. Feb., 1930.

"Some Classic Allusions to Milk," by James A. Tobey, Dr.P.H. *Trained Nurse*. Sept., 1930.

"The Acid Test," by Fassett Edwards, M.D. *Colliers*. July 19, 1930. To be "acid" or not to be.

"The Job and the Life Span," by Louis I. Dublin. *Harpers*. Jan., 1930.

"Vineland Experiments Aid to Science." *Trenton Sunday Times-Advertiser*. June 29, 1930. Illustrated page; training of mentally handicapped.

"Why Drown?" by Capt. Charles B. Scully. *Saturday Evening Post*. July 12, 1930.

CAMPAIGNS—DAYS

March 1, 1931, is the final date for reports on the 1930 Health Conservation Contest conducted by the Chamber of Commerce of the United States.

A colorful parade was the feature of a preschool celebration of Child Health Day at St. Joseph, Mo., as described and illustrated in *Red Cross Courier*, Washington, D. C., Aug. 1, 1930. *Free*.

Two features of the coming Christmas Seal Campaign will be a playlet by Mrs. Louise Brand of the Wisconsin Anti-Tuberculosis Association, and a Sam Lloyd puzzle contest to be put on by state and local committees.

In the National Negro Health Week the prize for the best observance in a city of more than 100,000 was awarded to Nashville, Tenn., which city won also the prize for the best observance in

all communities. Wichita Falls, Tex., won in the class under 100,000 population, and Kent County, Md., reported the best rural observance of the week.

A report on the Early Diagnosis Campaign of the tuberculosis associations shows that 4,531,432 booklets and 907,660 posters and posterettes produced by the National Tuberculosis Association were distributed, in addition to small quantities prepared by some of the state associations.

The coöperation of the newspapers, radio broadcasting stations, magazines, and life insurance companies was superb. While there is no way of checking the total national publicity, it is fair to say that it exceeded that of all previous years. Of the plate matter and special stories sent out, newspaper clippings indicate a wide use.

WHY DO THEY DO IT?

A state health department mimeographed bulletin comes rolled. With some effort one can unroll the darn thing—but it is a sight!

REPORTING

The Organization of a Rural Tuberculosis Service, by Stephen A. Douglass, M.D., is another of the delightfully printed, paper cover reports issued by the Milbank Memorial Fund, New York, N. Y. A distinctive feature of this report is the group of full page photographs without any distracting captions or titles. Curiously enough the addresses of the health staffs of Cattaraugus County are not given.

The solid black cover of the 1928-1929 report of the Henry Street Visiting Nurse Service (99 Park Ave., New York, N. Y.) is broken by a cut-out in the center which corresponds to the silhouette of a nurse in the center of the title page. About $5\frac{1}{2}'' \times 8''$; the Kabel Bold black-face type is striking for limited use; silhouettes on the 13 pages of text; 11 pages of easy-to-read financial statement, and management committees *with all names in caps and*

lower-case. The page "About Bequests" is unusually well done.

Says Maternity Center Association, 578 Madison Ave., New York, to its supporters:

As we are spending every available dollar on giving care to mothers in these hard times of unemployment, we are sending you this brief (and very inexpensive) account of our work for the year 1929 in lieu of our usual Annual Report.

The report is $5\frac{1}{4}'' \times 4''$, 12 pages, and accompanied by a large sheet listing names of contributors. *Free.*

Statistical Reports of Services, Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y. Again they illustrate how neatly and readably mimeographing and other processes can be used in presenting statistical data.

WRITE YOUR OWN HEADING

A way to make plain diagrams more picturesque is illustrated in "Underweight Children in Seattle," by W. W. Davis. *Hygeia*. Oct., 1930, pp. 937-940.

A topographic map of San Francisco is used to show location of playgrounds by the Playground Commission in its annual report. In contrast, on the opposite page is a street map of the city with its maze of streets and other fine detail. For some uses the topographic map brings a note of novelty and of clarity.

Recently *Editor and Publisher* offered the following "hunch" to newspaper editors:

How are babies marked for identification in the larger maternity hospitals of your city? How are the first 10 days spent in some of the leading institutions? A local story showing how the new babies arrive in the world in modern hospitals would be particularly timely and interesting.

A blotter appeal for a Henry Street Settlement camp (265 Henry Street, New York, N. Y.) makes an emotional appeal without "sobs." Four line cuts

show possibilities on a blotter. In adapting the blotter idea the cut-out flap could be omitted. Make the flap about two-thirds as large as the main blotter section, or merely double it. *Sample 2 cents.*

PLAYS

Mental hygiene was unusually and interestingly presented through a playlet entitled "My Son John" . . . at the annual convention of the National Congress of Parents and Teachers. The scenario was written by Dr. Lawrence Woolley, . . . and contained six scenes. The story revolved around 9-year-old Johnny whose family was disturbed by his frequent tantrums following an attack of illness and by his failing in school. A neighbor suggested that Johnny's mother seek the assistance of the local child guidance clinic, which she did. The subsequent scenes include the visit of the psychiatric social worker to Johnny's home; the psychiatric examination in the doctor's office; the customary staff conference on the case; and the psychiatrist's treatment interview with Johnny's mother.

. . . The audience was unanimous in expressing enthusiasm for this playlet as an educational medium of great value in getting across to that portion of the public which is uninformed about mental hygiene some of its essential features.

The playlet is being revised before publication by the National Committee for Mental Hygiene.

A Health play in which all the lines are chanted by the "Judge" offers a delightful and effective variation. "A Syncopated Health Trial," by Hazel M. Bowman. *Hygeia*. Oct., 1930, pp. 944-946.

PUBLICITY NEEDED

The responsibility in Cook County as elsewhere clearly rests in the first instance upon the citizens in whose neighborhoods these new centers of recreation (immoral road houses) are being located and no law enforcing officials, federal, state, or municipal, will be able to regulate or eliminate them without the *interested support of the public.*

—Cook County (*Illinois Roadhouses*, by J. F. Binford). *Journal of Social Hygiene*. May, 1930.

SOCIAL HYGIENE

In "Gaining a Public" (*Journal of Social Hygiene*, May, 1930), Ray H. Everett tells of experiences in the "dark ages" of the social hygiene movement, and describes later developments. The newspaper situation is thus pictured:

Such writers as Dr. William Evans and Angelo Patri, whose material reaches national audiences through syndication, have rendered great service to the movement. In fact Dr. Evans probably was the pioneer in the use of the straight-forward medical terms, syphilis and gonorrhea, in his press columns. It was a curious anomaly that many newspapers carried venereal disease advertising but refused to mention these words in their news columns. Such advertising is prohibited by law in most states today, but many editors still ban such words as "syphilis," "gonorrhea," "prostitution" and the like, one even going so far as to attribute an address by a noted professor of urology to "a well-known professor of social diseases." There has been a noticeable increase both in liberality and understanding during the past few years, however, and the time may soon come when a great majority of editors will have no more fear of an adequate social hygiene vocabulary than have a constantly increasing number of their readers.

"Innocent Children," in the same magazine, reproduces a brief syndicated article by Angelo Patri which, appearing in a number of newspapers, brought 1,800 requests for social hygiene information.

Another article, "1850-1930," is an interesting historical review prepared for use in social hygiene programs in connection with the celebration of Dr. Welch's 80th birthday.

Under "Exhibits" is an account of the charts and other wall display material prepared for the annual meeting of the American Social Hygiene Association. We hope that the Association will adopt the suggestion that this material be mounted on a revolving or loose leaf

displayer where it can be shown to interested people who call at the national office. The type of material and the form of display would then illustrate a valuable idea for state and national health agencies, for reaching professional and volunteer workers who call at such offices in the course of the year. Probably it would be well to provide one or several high chairs to make the experience more comfortable.

HOME-MADE POSTERS

A set of mimeographed health habit posters illustrates what might be done in many provinces and states. The mimeographed copies (on legal size sheets) may be colored, reproduced on the blackboard or on large cards or sheets, reproduced locally by mimeograph for wide distribution, or used to suggest posters to be made up from magazine pictures by the children. *Posters for Health Teaching—How to Make and Use Them* is a 2-page mimeograph memorandum. An example of sound advice:

If a single word or phrase is to be used, capitals are advisable, but for a sentence, use small letters. Allow space between words and lines.

All of the above from Health Education Service, Manitoba Department of Health and Public Welfare, Winnipeg. *Free.*

But why should not the above and other instructions on poster making include references to additional material available to the teacher, parent, or health worker who might care to get further ideas and help on the subject?

There are several books and several pamphlets on the subject—already mentioned in this department. Write if you wish them mentioned again.

BOOKS AND REPORTS

Tropical Medicine—By *Sir Leonard Rogers and John W. D. Megaw.* Philadelphia: Blakiston's, 1930. 536 pp. Price, \$5.00.

Within the year we have had three notable books on tropical medicine, the classical works of Stitt and Manson being revisions. The book before us will unquestionably take a high place in such literature, giving, as it does, the experiences of two well known men as the result of years of experience in both clinical and pathological work in India. They hold that the existing books on tropical medicine are better fitted for readers who are trying to qualify for diplomas than practising physicians.

They have departed from the cut and dried method of arrangement, and have classified diseases in accordance with their causal agencies, believing that it is more suitable to discuss amebic dysentery, for example, as an intestinal infection than with other protozoal diseases like malaria. Following this plan, tropical diseases are grouped in 11 sections, with such headings as: "Febrile Diseases caused by Protozoa," "Febrile Diseases caused by Spirochaetes," etc. This classification has much to commend it. The authors evidently believe in the historical method of teaching, and give considerable space to the history of tropical medicine.

The book is well written and eminently practical, in descriptions of the diseases as well as treatment, though there will doubtless be those who will not agree entirely with some of the statements. It is interesting to note that the authors are not carried away with some of the newer drugs which have been widely exploited, such as plasmoquin in malaria, Bayer 205 in trypanoso-

miasis, and yatren for amebiasis. There are others who will possibly object to the retention of some of the older terms in classification.

Some of the illustrations are excellent, but others could be improved. On the whole, we consider the book one of the best in its class, and believe that it will fulfil its aim.

While the authors state that they have collaborated closely in the preparation, and each assumes a general responsibility for its contents, they have signed the chapters of which they are the authors, and reserve the right to some differences of opinion, holding that tropical medicine has not yet reached a stage which permits ex cathedra pronouncements or claims to infallibility.

M. P. RAVENEL

Report on Fifth International Congress of Military Medicine and Pharmacy—By *W. S. Bainbridge, Commander M.C.F., U. S. Naval Reserve. Menasha, Wis.: George Banta Publishing Company, 1929. 154 pp.*

The Fifth International Congress of Military Medicine and Pharmacy met in London in May, 1929. This congress is assembled bi-annually, usually in the capital of some one of the participating nations. Its mission is to afford an opportunity for the interchange of ideas, experience and knowledge in all branches of military medicine. The Fifth Congress was composed of delegates from forty nations.

The report as prepared by Commander Bainbridge, a delegate from the United States, is principally a compilation of reports and communications submitted to the Congress on the subjects of Evacuation of Sick and Wounded by

Air and Water: Tropical Fevers of Short Duration; Injuries to the Blood Vessels and their Sequelae; The Physical and Chemical Analysis of the Glass and Rubber Articles employed by the Medical Services, and The Standard of Dental and Physical Fitness in the Various Military Services. These articles are all the result of thorough study by men well acquainted with the subjects under consideration; consequently, they contain much information of value to those interested in military medicine and should prove of interest to all members of the medical profession. The article on the Evacuation of Sick and Wounded by Air and Water is particularly good.

The book contains a number of very interesting illustrations showing sanitary appliances and methods of transporting wounded men. In the preparation and publication of this concise yet comprehensive paper, Commander Bainbridge has performed a valuable service for the medical profession in general and for the military medical services in particular.

G. C. DUNHAM

Proceedings of the Twelfth Texas Water Works Short School—Abilene, Texas, January 27-30, 1929. 189 pp. Price, \$1.00.

This publication is divided into two sections, one on water and the other on sewage. In the first section a number of subjects such as improvements in particular water supply systems, cross-connections and their control and elimination, developments in the treatment of highly polluted water, swimming pools, underground water supplies, water purification by chemicals, and disinfection of drinking water are covered. A particularly interesting paper describing the water works of the City of Mexico by three of the engineers in that service is worthy of attention.

In "Progress in Sewage Disposal," Ehlers gives the status of municipal sanitary improvements in Texas on Jan-

uary 1, 1930. This is complete and valuable for reference. Other subjects touched upon by speakers include the effect of gases on bacteria growth in sewage, lagooning sewage sludge, observations on the treatment of cannery wastes, and the advantage of sludge circulation and vacuum degasification.

ARTHUR P. MILLER

The Science of Biology—By George G. Scott, Ph.D. (rev. ed.) New York: Thomas Crowell Co., 1930. 633 pp. Price, \$3.75.

Here is a revised edition which the publishers advertise as "practically a new book." However this may be, the arrangement of material and method of presentation are not materially changed. The writing of a textbook on biology in one volume is a stupendous task, and at best can be little more than an outline guide which the instructor fills in as his knowledge permits. Professor Scott presents an inclusive outline filled in with interesting and suggestive details. As to the pedagogical considerations involved one not concerned in this field should express no opinion. The sections on eugenics and eugenics from the standpoint of public health should be carefully read as indicative of what is being taught those who may become leaders in this field.

N. W. LARKUM

Stalkers of Pestilence—The Story of Man's Ideas of Infection—By Wade W. Oliver, M.D. Introduction by Theobald Smith, M.D., Ph.D. New York: Hoeber, 1930. Price, \$3.00.

Medical history has a peculiar fascination. It reveals the twists and turns of the human mind, many leading into darkness, but fortunately most having a general trend toward the light; also the pestilences which took an almost unbelievable toll of life and tried the souls of men. Not only has disease been a powerful factor in directing the growth of civilization, but has determined the

geographical distribution of races, and frequently changed the history of the world. Civilizations have disappeared before the ravages of pestilence, as in Italy and Greece. Vast areas of fertile soil have remained practically uninhabited and uncultivated on account of malaria, as in the southern states of our own country.

The book before us is a reprint with additions and corrections from *The American Journal of Surgery*. It is an outline rather than a history, though it covers an enormous amount of ground. A number of brief sketches of the great physicians of the past, but also some arrant quacks, are given, and there are some names one would not expect to find, like Sir Isaac Newton and Charles Darwin.

The book is well written, well documented, abundantly and well illustrated, and correct as to facts; but we consider the name misleading. The most notable omissions, considering the title, are of those who have stalked pestilences from the administrative standpoint, and one can hardly excuse the failure to maintain Villemin and his epochal studies on tuberculosis.

The book is a contribution to the study of medical history, which received its great impetus in this country from the late Sir William Osler, and can be commended as a handy reference.

M. P. RAVENEL

Common Colds—Causes and Preventive Measures—By Leonard Hill and Mark Clement. London: William Heinemann, 1929. 121 pp. Price, \$3.00.

While the preface does not so state, it is to be presumed from the arrangement of the subject matter that the book has been prepared for lay reading. The retention of rather obsolete terms such as "choane" and "conchæ" strikes the reviewer as unfortunate.

As a whole, the book presents in brief

but readable form a symposium on the effects of proper hygiene on the prevention of the common cold. One illustration is rather unhappily chosen in referring to the adaptation of dress to the requirements of climate and occupation by the statement that "women have, in recent years, shown how little is required," inasmuch as the young women in the United States most clearly represented by the above statement are the only ones, as a group, to show an increase instead of a decline in the death rate for pulmonary tuberculosis during the past decade.

The plea for better ventilation, more sunshine, reasonable dress, balanced diet, and adequate exercise as the most adequate measures against the common and infectious cold is, for the most part, clearly and logically presented.

ALBERT G. BOWER

Ninth Annual Report of the Ohio Conference on Water Purification—Columbus, O. October 24-25, 1929. 107 pp.

This pamphlet is so full of interesting and instructive material that a review of it can only indicate what it contains. The water purification and softening plants at Fremont and Marysville are described and discussed, and one paper is devoted to the subject of maintaining a chemical balance in purified water so as to eliminate its corrosive tendency.

The troublesome problem of phenol in raw water is touched upon in two papers, one of which discusses removal of phenolic tastes, and the other the control of such tastes by increased lime treatment. Similar to these there are two others, one of which covers the taste and odor problem at Toledo, and the other, which is particularly timely, covers the ammonia chlorine process as a means for preventing tastes and improving sterilization.

Due to the increased importance of swimming pools, two papers are devoted

to them, one on swimming pool sanitation and the other on design.

Several pages are devoted to miscellaneous plant problems.

ARTHUR P. MILLER

Physiology and Biochemistry of Bacteria, Vol. II and Vol. III—By R. E. Buchanan and Ellis I. Fulmer. Baltimore: Williams and Wilkins, 1930. Vol. II, 709 pp. Price, \$7.50. Vol. III, 575 pp. Price, \$7.50.

Volume I of this series appeared in 1928 and was reviewed in this JOURNAL January, 1929, p. 129. All that was said regarding Volume I applies to the other volumes. The authors have now completed the task they set out to accomplish, namely, the collection and evaluation of available information concerning the more fundamental properties of bacteria and the principles governing bacterial action. When one picks up Volume II with its more than 700 pages and reads in the preface that space limitations forbid elaboration in a treatise intended to serve merely as an *introduction* to the subject, one wonders how extensive a publication would be required to include the details which this volume introduces.

There is no question as to the value of these books as works of reference. The extensive bibliography alone is of exceeding worth, but however interestingly they may be written the number of readers is bound to be limited.

N. W. LARKUM

Sleep. Why We Need It and How to Get It—By Donald A. Laird and Charles G. Muller. New York: John Day, 1930. 214 pp. Price, \$2.50.

The presentation of the material recorded by these authors represents an interesting experiment in bringing the results of scientific experimentation before the general reader in such form that it challenges his interest. The sub-title and chapter headings use the terms of

our everyday language and are arranged in approved attention arresting phraseology. The short snappy sentences serve as excellent stimulation to counteract the soporific nature of the subject matter so that at no time is there any tendency for the attention to lag, and although not "primarily adventure or detective" cannot be used as suggested by its authors in the chapter, "When It's Hard to Get to Sleep."

The recommendations included in Part IV, based on the results of their scientific experiments, assume a form of expression calculated to arouse determination to follow them out to the letter. Anyone with an introspective or reflective turn of mind would find this fascinating reading, and one feels urged to recommend the whole book. The instructions for obtaining relaxation are found detailed and simple. One wonders if following them would be sufficient to bring about a degree of relaxation in those who really need it. To one who has never had any difficulty in getting to sleep, or in remaining asleep, the entire book sounds plausible and the instructions reasonable.

To one accustomed to reading descriptions of experiments in the classical form, with detailed description of apparatus and procedure, the book is likely to give the impression of being an interesting record of facts incompletely supported by experiments. This criticism has apparently been anticipated in the introduction. Unlike most books covering scientific subjects in a popular manner, the subject matter is so presented that one has the same stimulus and the same interest in knowing whether these experiments have been performed by others and the results confirmed or contradicted.

Although the experimenters seem to have provided for a percentage of error due to the human equation in the use of the special type of "guinea pig," one would like to know the results of others.

in the same field. There is some adherence to the form of scientific presentation in that the work starts out with a review of theories held in the past, with references to literature and the description of typical experiments given in the appendix. The bibliography itself is of no small value.

While the book makes no claim to consideration as a medical treatise, one who is forced to think of it from that point of view is impressed by the lack of any reference to possible physical disorders as a cause of insomnia, and the importance of eliminating these, or of seeking appropriate medical attention before following the advice given.

One also wonders why anyone who appears to have had extensive training in the fields of biology, psychology and education, but without medical training, should be described as having engaged in "psychiatric testing," whatever that may be.

The book is published in convenient, attractive form and the type so arranged that it is pleasing and restful to the eye. It seems particularly timely, when communities are becoming aware of the tremendous amount of unnecessary noise. HELEN P. LANGNER

The New Evolution, Zoogenesis—

By Austin H. Clark. Baltimore: Williams & Wilkins, 1930. 297 pp. Price, \$3.00.

In reviewing this book, one is confronted at the start with a controversial question. The question is not only controversial as to the actuality of evolution, but more especially as to the mode. Evolution at best is not accepted by millions of laymen, and to come forward with a "New Evolution" is likely to confuse rather than to clarify. Again, to advertise the book as being "As Epochal as Darwin" is to lend prestige indeed.

Despite the foregoing, the book is extremely interesting, and was written by

one of America's leading scientists. The point is made by some that the author's chief work has been among the crinoids, but we fail to see how this prevents him from being a good evolutionist. This reminds one of an occasion when one of our leading entomologists was visiting in Italy where he was introduced as "an American entomologist who knows something about biology." As if knowing something about biology were beyond the average entomologist! No special field of biology has a monopoly on knowledge of evolution, and as Dr. Clark's contributions have been in many corners of the biological world he cannot be charged with being a narrow specialist. From this broad touch he has brought a multitude of facts portrayed in such manner as to be easily understood by the average reader.

The outstanding point Dr. Clark makes is, in his own words: "Life in its very first beginnings developed at once and simultaneously from the primitive single cell in every possible direction, giving rise to some original form or forms in every phylum. So at its very first appearance animal life assumed essentially the same form as that in which we know it now so far as the phyla or major groups of animals are concerned" and "No matter how far back we go in the fossil record of previous animal life upon the earth, we find no trace of any animal forms which are intermediate between the various major groups. . . ."

If the absence of connectant forms in the geological record is a stumbling block, with reference to the affinities of the major groups, how does Dr. Clark relate the fishes, amphibians and reptiles with his "primitive single cell"? These three groups, to say nothing of many other higher vertebrate animals, do not extend back beyond the paleozoic, yet there is a vast expanse of time between the paleozoic and the time when life first arose.

It is a bit unfortunate to say "there

is not the slightest evidence that man is descended from an ape," because there is no real controversy here, but the lay reader would be justified in assuming that there is one. The present data as to man's zoölogical relationship have to do largely with certain fossil forms found in various parts of the earth. Among these are the "southern ape" of South Africa, the "Java ape-man," the Piltdown man of England, the Heidelberg man that comes from the second interglacial period, and the Neanderthal man of the third interglacial period, the last resembling man so closely that it is placed in the same genus under the name of *Homo neandertalensis*. With reference to this creature, Dr. A. S. Romer, of the University of Chicago, says: "He is a man, in the broad sense, but a man with the mark of the ape upon him." Romer believes that this Neanderthal man and our species had a common Asiatic (or African) ancestor. The point is, man *did* have an ancestor that was different from man's present state; so who cares whether he was an ape or a baboon?

Although this book is crowded with interesting facts, we suggest, for the lay reader, that it be preceded by some book written more from the standpoint of an introduction to the subject of evolution in its various forms. C. F. ADAMS

The Principles and Practice of Hygiene—By Dean Franklin Smiley, Adrian Gordon Gould and Elizabeth Melby. New York: Macmillan, 1930. 415 pp. Price, \$2.50.

Although not indicated in the title, the preface and the context make it clear that this book is intended chiefly for nurses. We agree entirely with the authors' statement concerning the importance of health instruction in the nursing curriculum. It is perfectly true that nurses have opportunities enjoyed by no other class, physicians not excepted, for teaching the principles of

hygiene and good living. The necessary exposure which every nurse must incur makes her own protection important, and this personal phase is emphasized. The authors also feel that the nurse should know how and what to teach for the foundation of health.

Looked at from the points of view enumerated, the book is adequate. In some respects it lacks balance. Immunity, including the various vaccines, is given only 14 pages, and this is all that is said about 11 diseases, including such important ones as diphtheria, scarlet fever, meningitis, smallpox, and measles. Less than two lines are given to rabies, and one would suppose from the statement that the vaccine was produced by growing the organisms at unfavorably high temperatures, or in weak antiseptic mediums. Since the curriculums of many schools of nursing are woefully deficient in time given to bacteriology and the methods of its presentation, we believe that this chapter is inadequate. Each chapter ends with a summary which we fear will conduce to laziness, since the student will read this only. However, it is a useful feature where rapid reference is desired.

The book is well printed and made up. The illustrations are sufficient and good. Altogether, the book can be thoroughly commended in its class.

M. P. RAVENEL

Pioneers of Public Health. The Story of Some Benefactors of the Human Race—By M. E. M. Walker. With Foreword by Sir Humphrey Rolleston. Edinburgh and London: Oliver and Boyd, 1930. 270 pp. Price, \$5.00.

A book of this type inevitably brings to mind the *Psalm of Life*. Biographies are always interesting and generally useful. The question of selection of subjects comes foremost. The scientists of whom the author writes were suggested by the fact that their names are in-

scribed on the walls of the new building of the London School of Hygiene and Tropical Medicine. Of 21 men, 12 are British, 4 from the United States, 3 from Central Europe, and 2 from France. There can be no fault found with the selections as far as they go, though one might well wish that other names had also been included.

The volume begins with Thomas Sydenham, "the English Hippocrates," and, as the author suggests, some might have preferred that it be headed by Hippocrates himself.

Due credit is given to the laymen, Chadwick in England, and Shattuck in America, who did so much to show the evil effects of poverty and poor health and the necessity of rational preventive medicine. We believe also that the author has done well to confine his list to those who have been dead long enough to allow a critical world to weigh justly their merits.

The weakest biographies in the book are those of the Americans. One would suppose, for example, that General Gorgas accepted the work of Reed at once, yet "his conversion was slow," and he did not begin anti-mosquito work until two months after General Wood's General Order No. 6, December 21, 1900. He persisted in the disinfection of beds, clothing, etc. until the middle of August, 1901, though orders had been issued by Colonel Havard, Chief Surgeon, in April, for its discontinuance. The first attempts at controlling yellow fever in Havana by cleaning the streets, patios and buildings were not successful, and after the thorough cleaning up, one of the most severe epidemics of recent years took place. Carlos Finlay had said that the work was along the wrong lines, and only measures against the mosquito would give the desired results. It took the epidemic to convince those in charge of the truth of this statement.

It is to be regretted that a book pub-

lished in 1930 should perpetuate the fallacy put forward by Noguchi in 1918, concerning the causative organism of the disease. In view of the work of the Commission on Yellow Fever under the auspices of the International Health Division of the Rockefeller Foundation, and others, there seems to be no excuse for this.

There are also a number of minor errors, particularly in the biographies of the Americans, in the spellings of names and positions occupied. The old term "stegomyia fasciata" is retained for the yellow fever mosquito.

The book is delightfully written. There is not a page that does not hold the attention. The illustrations are excellent and the printing and make-up of high quality. M. P. RAVENEL

Elementary Materia Medica, Including Drugs and Solutions—By Walter W. Kruger, Ph.B. Philadelphia: Saunders, 1929. 278 pp. Price, \$1.75.

Among the many elementary textbooks on the market, the one under review ranks with the best. The material treated, and the manner of its arrangement, constitute the development of a course given to nurses during the past six years.

In addition to a very proper historical and theoretical background, the practical application of all facts presented is held of first importance, and rightly so. It is one thing to know something about elementary materia medica and solutions; it is another one to be able to apply this information.

There are 20 chapters, an appendix and an index. Each chapter is concluded with a set of questions and a brief bibliography, while chapters 19 and 20 consist wholly of "Problems for Review" and "Laboratory Exercises and Demonstrations." The appendix is a "General Bibliography" of the more important works bearing on the subject.

The most usable chapters consider such subjects as pharmaceutical preparations, arithmetic review, weights and measures, solutions, preparation of solutions, antiseptics and disinfectants, doses and their preparation and the administration of medicines, although various other subjects are quite adequately treated.

The book is reasonably free from errors, fairly well illustrated and, upon the whole, a very useful publication on elementary *materia medica*.

C. F. ADAMS

The Human Factor in Industry—

By E. P. Cathcart, C.B.E., M.D., F.R.S. New York: Oxford University Press, 1928. 105 pp. Price, \$1.75.

The several chapters of this small book are based upon two series of lectures given in the Engineering Department of Glasgow University. "We are still far from the day envisaged by Butler in *Erewhon* when man will be reduced to the status of a mere 'machine-tickling aphid.' " Man must always be variable in every calculation involved in industrial production. He is not a machine but a sentient being.

The five chapters are devoted respectively to physiological considerations (in industrial relations), fatigue and monotony, alleviation of fatigue, environmental factors (in fatigue), and industrial personnel. There is also an Appendix upon "The Living Wage," and an appended Bibliography for each chapter. A great majority of the illustrative instances used in the text have been taken from the Reports of the Industrial Fatigue Research Board.

In the average workshop the hardest work is most often done by the worst paid worker whose mechanical efficiency cannot possibly exceed 20–25 per cent of his caloric intake. The pure brain worker apparently requires no additional intake to cover the expenditure

of mental energy. Man is really a "psychic chameleon," relatively few really thinking, and most taking their ideas second-handed. The complications of this situation are subjects of interesting physical and mental analysis.

Numerous short tables and diagrams serve to illustrate the economic side of human efficiency at work. At present, selection tests are often ludicrous: in the case of 6 managers interviewing 36 candidates for posts, 1 was rated as number 1 and 32, and another as 3 and 30, in their respective estimations. In short, important factors concerned with industrial fatigue and their practical solution in industry compose the theme of discussion throughout the book. There are many American as well as Continental citations of the author's theme and conclusions.

The book is a very readable and concise discussion, by a leading physiologist, to a non-medical audience, and is also valuable as a source book of recent facts, theories, and experiences.

EMERY R. HAYHURST

The Bacteriophage and Its Clinical Applications—By F. D. d'Herelle. Springfield, Ill.: Charles C. Thomas, 1930. Price, \$4.00.

Each chapter in this book corresponds to one of the Lane Lectures delivered at Stanford University, October, 1928. It is addressed especially to practitioners of medicine, and presents the perplexing problem of these intracellular particles.

The revolutionary views of the author can be seen from the following quotation (p. 6):

The cellular theory of life is manifestly false, for life is an attribute of intracellular particles. The antibodies play no part in the phenomena of recovery. The form and the properties of bacteria are inherently variable characters.

He presents the reasons for and against the living character of the bacteriophage corpuscle, holding that the

bacteriophage is a corpuscle (micellum) possessing autonomy; has its own characters which it transmits to its descendants, and is completely independent of the bacterium at the expense of which it multiplies. It possesses powers of adaptation. It secretes a lysin, and thus has the same agency for assimilation as other living beings. If adaptation, assimilation and multiplication define life, why, then, can it be maintained that the bacteriophage is not a living being? Philosophically, the author answers (p. 97):

We do not yet know what life is, that is to say, as yet we have not succeeded in identifying the physico-chemical property which confers upon the protoplasmic micella the faculty of assimilation.

The results thus far obtained with bacteriophage therapy in infections of the enteric tract and in those due to the organisms of the enteric group are summarized as: (1) specific for bacillary dysentery; (2) specific for Asiatic cholera; (3) of little value in the typhoid and paratyphoid fevers; (4) highly effective in acute colon; (5) promising in infantile diarrheal conditions and in enterocolitis; (6) upon the basis of a limited experience appears effective in sprue.

Three factors appear to play an important rôle in the effectiveness of bacteriophage treatment: virulence of the phage, mode of administration, and time of treatment. A disregard of these seems to account for at least some of the failures.

The action of the bacteriophage can be stated as resulting in: the dissolution of the bacteria; enhancement of opsonic power, a refractory state of more or less

duration in the host due to the bacterial proteins of the disintegrated bacteria. It induces modifications of the characters of bacteria, whenever it establishes symbiosis with a bacterium, though these seem to occur in an apparently irregular fashion. The author claims that bacterial mutations are produced exclusively through the action of the bacteriophage.

The author points out the importance of bacteriophagy to pathology, immunology, epidemiology and hygiene. Its study will not only force a new appraisal of theories, but will initiate research and hope in a cure for diseases, especially of the persistent chronic type, e.g., tuberculosis.

The reader who is interested in studying further the problems of bacteriophagy can find much more material in the detailed account by d'Herelle, *The Bacteriophage and its Behavior*. In it he will also find references to the work of the authors referred to in this book.

ESTHER W. STEARN

Pettibones Physiological Chemistry
—By J. F. McClendon, Ph.D. St. Louis: Mosby, 1929. 368 pp. Price, \$3.75.

This fourth edition of Pettibones textbook has been developed from the course in physiological chemistry as given in the Medical School at the University of Minnesota. It is intended as an intermediate text covering both the theoretical and practical laboratory work in physiological chemistry, as taught at Minnesota, and has been revised and brought up to date by McClendon.

R. W. PRYER

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Syracuse, N. Y.—A table of contents, an index, and numerous charts and graphs make easy the study of the annual report of the Department of Health for 1929. The estimated population of 201,645 establishes Syracuse as the fourth largest city in New York State, with a 1929 birth rate of 21.0 and a crude death rate of 13.0. The infant mortality rate of 55.7 and the tuberculosis death rate of 57.5 were the lowest ever attained in the city.

The Health Department appropriation for 1929 was \$293,000 (\$1.47 per capita), of which \$33,000 was received from the Milbank Memorial Fund. The diphtheria immunization campaign, begun in 1923, has resulted in protective treatments being given to 27,372 children. Only 19 deaths have occurred from diphtheria in the past 5 years.

New cases at the well baby clinics in 1928 were 1,125, with 6,854 clinic visits, more than one-half being brought to the clinic before the child was 3 months of age. The summer round-up of children expecting to enter school in September has necessitated the employment of additional physicians, making possible 9 preschool clinics a week.

Chelsea, Mass.—The 1929 annual report of the Board of Health of Chelsea is made up primarily of tabular material. Based on an estimated population of 47,247, a death rate of 11.72 per 1,000 living, exclusive of stillbirths, is recorded. Corrected for residence, the rate is lowered to 6.77.

During the year a milk regulation was passed requiring that all raw milk, offered for sale in the city, be from tuberculin tested and accredited herds, or tested herds on the way to accreditation under state and federal supervision; that

it be certified by a medical milk commission in a manner required by law; that when offered for sale it shall contain not more than 10,000 bacteria per c.c.; and that all milk not meeting these requirements be pasteurized.

Of 11,049 defects found in examining school children, 5,017 were corrected during the school year 1928-1929.

Schenectady, N. Y.—The health activities for the year ended October 31, 1929, are portrayed in a gray covered report of 45 pages. This city with an estimated population of 95,849 reports 140 more deaths during 1929 than in 1928, or an increase in the rate from 10.96 to 12.33 per 1,000. Heart disease and cancer, with increases of 32 and 18 respectively, accounted for one-third of this increase. Pneumonia followed with 29 deaths, influenza 21, tuberculosis 7, and automobile accidents 7. A birth rate of 17.52 per 1,000 and an infant mortality rate of 72 are recorded.

The supervisor of nurses, in her report to the health commissioner, states that for a long time there has been need for more nurses to do clinic work as well as work in the district, and that this need has been particularly urgent in the tuberculosis division.

The Committee on Tuberculosis and Public Health came to our aid and in July appointed a nurse to help reorganize this division. The old files were gone over and many old cases were again taken up. All cases that had been reported during the past 10 years were investigated and all contacts, especially children, were asked to have an examination, either by their own family physicians or at the health center. One of the real needs at present is a preventorium for children who are not in good physical condition and yet are not tuberculous.

A modern abattoir has been con-

structed during the year where animals may be slaughtered under more cleanly aseptic surroundings, and the meat carefully inspected, and stamped before being offered for sale to the public. A veterinarian has been added to the health department staff.

An increase is shown in the amount of milk sold daily in the city, approximately 4,500 quarts being consumed, more than one-half of which is delivered to homes. Eighteen hundred half-pints of milk are delivered daily to the schools in the city.

Worcester, Mass.—During 1929, Worcester showed considerable progress along health lines, according to the annual health department report. Sanitation has been improved since the completion of a new Decarie type plant for the incineration of rubbish. Finances have been appropriated for the purpose of adding a new wing containing 100 beds to the tuberculosis ward of Belmont Hospital. This addition will provide further accommodation for persons with incipient tuberculosis, and also will meet the requirements of the State Department of Health.

In general, the number of cases and deaths from communicable diseases has decreased. Diphtheria has dropped from 309 cases with 28 deaths in 1925 to 108 cases with 6 deaths in 1929, while scarlet fever has decreased from 631 cases with 16 deaths in 1924 to 311 cases with 2 deaths in 1929. The birth rate for the city during the year was 19.50, the death rate, corrected for residence, 10.08, and the infant mortality rate 61.55.

Preschool work, which includes the diphtheria immunization clinics and summer round-up clinics for children about to enter school in the fall, shows continued progress, as does the work with children of school age. An additional dental hygienist has been appointed, who will be available for class

instruction under the supervision of the dentists. Interspersed throughout this report are barred diagrams in black and white, which not only supplement the text, but add to the attractiveness of the report.

Wood County, W. Va.—The annual report of the Wood County, W. Va., Health Department is a concise, well assembled and very readable one of 16 pages. The department personnel consists of a health officer, 2 inspectors, bacteriologist, county health nurse, and clerk. The per capita cost of public health work is 24 cents.

Dairy herds are tuberculin tested once a year. All milk and milk utensil handlers are examined. Of the milk samples examined, 76 per cent gave counts less than 100,000 bacteria per c.c. Inspections of dairies and other food handling places totaled 592, other sanitary inspections totaling 585.

Immunization treatments against disease were as follows: anti-typhoid 700, antismallpox vaccinations 600, toxin-antitoxin 4,200, diphtheria antitoxin 17, antirabic 2. School examinations, made as often as possible, are somewhat limited because of severe weather and distance. The number of schools visited by the physician and nurse was 193, in which 3,496 pupils were inspected; 1,567 being examined by a physician. Examination results with accompanying suggestions are sent to the parents, personal contacts being impossible because of the lack of personnel. Of the 15,000 defects found, 750 were corrected.

Thirty preschool conferences were also held. At least one venereal disease clinic is held each week, the average attendance being 30.

Marion County, Ore.—The Marion County Health Unit has prepared an attractive 35 page report for 1929, which shows the organization to be com-

posed of a health unit committee of 8 members, a health officer and deputy, a school dentist, 8 staff nurses and 1 supervisor, milk and food inspector, sanitary inspector, and 2 office clerks. The total appropriation for health during the year 1930 was \$40,175, or \$.80 per capita. Local funds will total \$30,985, an increase of \$8,200 over 1929, while the remainder will be spent by the Commonwealth Fund.

The death rate for Marion County in 1929 was 13.1 per 1,000 population, the birth rate, 15.6. The 1929 infant mortality rate was 39.7 per 1,000 live births, as compared with 48.0 for the state of Oregon. The tuberculosis death rate for 1929 was 40.0 per 100,000 population. The county for the same year experienced no deaths from smallpox, 1 from diphtheria, 2 from measles, 1 from typhoid, and 382 from the so-called degenerative diseases. No deaths oc-

curred from scarlet fever. A special survey was made to locate tuberculosis cases and contacts, in which the physicians in the county coöperated in early reporting, and a weekly chest clinic has been effective.

With the passage of a suitable milk ordinance in 1928, considerable progress has been made toward enforcement and in assisting in improving milk quality. By January 1, 1930, 83 per cent of milk sold in Salem was pasteurized, and all raw milk showed a bacterial count of less than 50,000. Inspection of highway tourist camps is a sanitary task here as elsewhere. In addition to 32 such tourist camps, over 100 other temporary camps, maintained by berry and hop growers, required supervision. The A. P. H. A. appraisal score for Marion County for 1928 was 754 out of a possible 1,000, a gain of 49 points over 1927.

BOOKS RECEIVED

TROPICAL MEDICINE. By Sir Leonard Rogers and John W. D. Megaw. Philadelphia: Blakiston, 1930. 536 pp. Price, \$5.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Enuresis Studies—An exhaustive research in the psychiatric aspects of enuresis, dealing with age, sex, physical, pathologic and social factors as related to this condition.

ANDERSON, F. N. The Psychiatric Aspects of Enuresis. *Am. J. Dis. Child.*, 40, 3: 591 (Sept.), 1930.

Maternal Hygiene Standards—Excerpts from a committee report with the recommendations for prenatal care given in full.

ANON. Standards for Maternity Care. *Child Health Bull.*, 6, 5: 146 (Sept.), 1930.

Psittacosis—An excellent statement of what is known of the epidemiology, infectivity, diagnosis, prognosis and prevention of this unusual disease.

ARMSTRONG, C. Psittacosis: Epidemiological Considerations with Reference to the 1929-30 Outbreak in the United States.

Dental Caries—Diet including green vegetables, fruit and milk and low in sugar is inhibitive to dental caries. Is this the result of a decrease in aciduric bacteria in the mouth, the increase in salivary alkalis or the hardening of the teeth? The underlying theory is less important than the practice.

BUNTING, R. W., *et al.* The Problem of Dental Caries. *Am. J. Dis. Child.*, 40, 3: 536 (Sept.), 1930.

Milk-Borne Epidemics—Reporting the occurrence of milk-borne epidemics from 1924-1929, 44 new outbreaks are added to the 214 recorded in the previous 5 years; an unenviable record.

CRUMBINE, S. J. Milk-Borne Epidemic Diseases in the United States and Canada Reported by the State and Provincial Health Authorities, 1924 to 1929. *Child Health Bull.*, 6, 5: 157 (Sept.), 1930.

Arthritis Symposium Continued—The excellent symposium on arthritis (reported in the September Bibliography, q.v.) is extended to cover additional subjects in the diagnosis and treatment of this condition. Together, the two installments form a most inclusive and authoritative discussion of this important field of public hygiene.

CECIL, R. L., *et al.* Symposium on Arthritis—Continued. *J. Lab. & Clin. Med.*, 15, 12: 1177 (Sept.), 1930.

Diphtheria Distribution—Evidence is presented showing that variation in diphtheria prevalence is associated with dosage and host-resistance. Examples are also given in which the determining factor is obscure. An excellent dissertation.

DOULL, J. A.. Factors Influencing Selective Distribution in Diphtheria. *J. Prev. Med.*, 4, 5: 371 (Sept.), 1930.

Effects of Tonsillectomy—A 10-year follow-up study indicates that tonsillectomy reduces the chances of sore throat, scarlet fever, diphtheria and rheumatic fever, has no beneficial influence on the incidence of head colds, and that respiratory infections such as laryngitis, bronchitis and pneumonia occur more frequently in tonsillectomized children.

KAISER, A. D. Results of Tonsillectomy. *J. A. M. A.*, 94, 12: 837 (Sept. 20), 1930.

Cancer of Lip and Tongue—The author discards smoking as the cause of cancer about the mouth; she discounts the influence of syphilis; and leaves the jagged tooth theory suspended.

LANE-CLAYTON, J. E. Cancer of Lip, Tongue and Skin. Ministry of Health (British) Reports on Public Health and Medical Subjects, No. 59, 1930.

School Health Programs—An excellent picture of a unified health program including school sanitation, physical education, health instruction and health supervision at an estimated minimum cost of \$7 per child. The aims—less illness, greater efficiency and happiness.

KEENE, C. H. A Program for School Health. *Pub. Health Nurse*, 22, 9: 444 (Sept.), 1930.

British Health Service Opportunities—A frank statement of the possibilities for a career in the public health service precedes an outline of the educational requirement for the D. P. H. in Great Britain.

KERR, H. The Public Health Service as a Career. *Med. Off.*, 44, 10: 97 (Sept. 6), 1930.

Mental Hygiene in Toronto—How mental hygiene is incorporated in the work of the public health nurses of the Toronto Department of Public Health is well told in a paper discussing the broad issues of mental health.

LEWIS, E. P. Mental Health. *Pub. Health Nurse*, 22, 9: 458 (Sept.), 1930.

Preventing Diphtheria in Lowell—How 25,000 children in Lowell were immunized at an approximate cost of 7 cents per child is recorded in painstaking detail.

MCMAMARA, J. J., and SULLIVAN, G. M. Diphtheria Prevention in Lowell, 1928 and 1929. *New Eng. J. Med.*, 203, 9: 413 (Aug. 28), 1930.

More About Rheumatism—Still another symposium on rheumatic fever, this time a British discussion.

MILLER, S., *et al.* Rheumatism in its Public Health Aspects. *Pub. Health* 43, 12: 377 (Sept.), 1930.

Dietary Facts and Fancies—A useful review of dietary knowledge exposing the food faddists.

STONE, W. J. Dietary Facts, Fads and Fancies. *J. A. M. A.*, 95, 10: 709 (Sept. 6), 1930.

Status of Scarlet Fever Prophylaxis—Nothing new is reportable to change the attitude of the conference of state and territorial health officials expressed in 1926, to wit: the Dick test is a fairly dependable indication of the immunologic status; scarlatinal streptococcus toxin will immunize susceptible individuals; the value of antitoxin for passive immunization is not sufficiently proven.

VELDEE, M. V. The Present Status of Streptococcus Biologic Products in the Prevention and Treatment of Scarlet Fever. *Pub. Health Rep.*, 45, 32: 1827 (Aug. 8), 1930.

Silver Polish Poisoning—A number of cases of poisoning thought to be due to foods were later found due apparently to the use of tableware on which a cyanide silver polish had been used. This leads to the warning against the use of polishes containing this material.

WILLIAMS, H. Cyanide Poisoning, Acute and Non-Fatal, Apparently from Hotel Silver Polish. *J. A. M. A.*, 94, 9: 627 (Mar. 1), 1930.

Cultural Characteristics of Diphtheria Bacilli—"Smooth (colony) virulent, toxic diphtheria bacilli are transformed to non-virulent, 'R' (rough colony) forms in the throats of patients during convalescence." Vaccination of carriers of the smooth colony forms with an "S" vaccine is suggested.

YU, H. A Study on the Dissociation of the Diphtheria Bacillus. *J. Bact.*, 20, 2: 107 (Aug.), 1930.

NEWS FROM THE FIELD

WISCONSIN MEDICAL SOCIETY

AT the meeting of the State Medical Society of Wisconsin, September 9-11, Dr. C. A. Harper, State Health Officer, was elected President. At the annual banquet, Dr. A. W. Rogers, in the name of the society, presented him a gold medal in the following words:

A son of Wisconsin, a practicing physician since 1894, appointed to the State Board of Health in 1907 by Governor La Follette and serving continuously since with no appointments from Governors Davidson, Philipp, Blaine and Kohler; for your twenty-nine years of membership on that Board, twenty-seven years as Secretary, for your closer vision, for your careful and untiring work in the interests of all people as Health Officer of this state, and for your service as a counselor and officer of your State Medical Society, we, your fellow members, give you this seal of our Society as a token of your achievements, and our esteem and affection.

ARGENTINA ESTABLISHES A "MODEL INSTITUTE OF MATERNAL AND CHILD HYGIENE"

THE President of the National Department of Hygiene of Argentina has recently ordered the establishment of a "model institute of maternal and child hygiene."

The institute will have a practical school for the training in child care of physicians, nurses and dietitians.

It will also provide continuation courses for physicians who are in charge of child health centers, and will organize traveling centers for maternal and child hygiene in the rural districts of the country.

WEST VIRGINIA NURSES

OCTOBER 23-25, the State Nurses Convention met in Fairmont, W. Va., and many interesting papers were presented.

NURSES' GRADING STUDIES

IN her paper entitled "The Student's Share," May Ayres Burgess has presented, through graphs, the amount of time spent by the student in the various nursing services. This appears in the October issue of the *American Journal of Nursing*.

ROENTGEN PIONEER

DR. Christian Deetjen, pioneer in the study and use of the Roentgen or X-ray, had his right arm amputated at the elbow as a result of his medical research. This is reported to be the eighth operation he has undergone due to his research work.

LUNG MACHINE

PHILIP Drinker, A. P. H. A. member, of Harvard, has invented a respirator, an airtight metal box mounted on wheels, big enough to contain a man, leaving his head out. Its purpose is to prolong artificial respiration beyond the period possible by manual methods. It was demonstrated recently before a delegation of police and fire surgeons in Boston.

STANDARDS FOR MATERNITY CARE

A REPORT has just been published on Standards for Maternity Care, prepared by the Committee on Maternity Care of the Children's Welfare Federation and a Committee appointed by the New York Obstetrical Society. This is a 32-page booklet published by The Children's Welfare Federation, 244 Madison Avenue, New York, N. Y.

NURSING CALENDAR

THE National League of Nursing Education has prepared an attractive calendar for 1931. This includes unpublished pictures of Florence Nightingale's birthplace, the Villa Columbaia, in Florence. The price is \$1.00 for a single copy, \$.75 in quantities over 50. National League for Nursing Education, 370 Seventh Avenue, New York, N. Y.

MOTOR FATALITIES

DEATHS from automobile accidents in the United States in 1930 will probably total about 33,000, and there will be more than 100,000 accidental deaths in all. So Dr. Louis I. Dublin reported to the National Safety Council at its meeting in Pittsburgh on September 29.

PARROT HAS HEALTH CERTIFICATE

A PARROT was recently brought into the United States with four health certificates. It had been bought in Belgium, and one of the certificates was from the Belgian Government.

PERSONALS

KARL F. MEYER, PH.D., director of the Hooper Foundation for Medical Research, has been appointed chairman of the committee on undulant fever of the National Research Council.

DR. MARTIN J. LACEY has been selected as health officer of Albany, Calif., succeeding Dr. Jack L. Stein.

DR. LINDLEY H. ESHLEMAN has been

appointed city health officer of Marion, Ind.

DR. FRANK L. WATKINS, director of health education in the public schools of Tulsa, Okla., was recently elected city-county health officer of Great Falls to succeed Dr. Thomas F. Walker. Dr. Watkins was formerly in charge of the Ohio Bureau of Vital Statistics and was affiliated with the Mississippi and Florida state boards of health.

J. H. SHRADER, PH.D., M.D., has been appointed Associate in the Department of Chemical Hygiene in the Johns Hopkins School of Hygiene and Public Health, to teach the course, Public Health Aspects of Food Production and Distribution.

DR. H. JACKSON DAVIS, who has been epidemiologist for the New York State Department of Health, has become Acting Health Commissioner of Cortland Co., N. Y., during the absence of Dr. Daniel R. Reilly, who, under a Rockefeller Foundation Fellowship, is taking a year's course in the Johns Hopkins School of Hygiene and Public Health.

CONFERENCES

Oct. 30-Nov. 1, American Water Works Association, California Section, Annual Convention, Pasadena, Calif.

Nov. 19-22, White House Conference on Child Health and Protection, Washington, D. C.

Nov. 30-Dec. 6, Asociacion Medica Mexicana, Guadalajara, Jalisco, Mexico.

People who read this amusing little book should

Have Fewer Colds This Winter

When we refer to Mr. Smith's adventure as a "case," we mean that Mr. Smith had a bad cold in the head.

In fact, as the author says, "Besides having a bad cold in the head, Mr. Smith also had a wife, Mrs. Smith, who also had a cold in the head, and a daughter, Elithabeth Thmiff, who thome-how alwayth had a code in the heb. . . ."

Yet, "the Smiths *always*

wore their rubbers . . . they were *always* rubbing their chests with something . . . they *never* sat in a draught . . . and in cold weather all three wore their prickly underwear.

"So *how* did the Smiths get their colds?"

Whoever you are, health worker, teacher, mother or just ordinary citizen, we urge you to send for this highly amusing yet thought-provoking little

booklet. Find out as the Smiths did how you get your colds . . . or how you may help others to take the precautions that they should.

Here is excellent early-winter reading for anyone. So mail the coupon promptly for your *free* copy of "The Strange Case of Mr. Smith." (Additional copies by special request or at cost.)

Time, Coöperation and Research Measure Success in Health Work*

A. J. CHESLEY, M. D., F. A. P. H. A.

State Health Officer, St. Paul, Minn.

THE slogan: "All things come to him who waits" is all right for a "tree-sitter," but Lindbergh preferred the World War slogan: "Let's go!" "It won't be long now," the newspapers said, when Lindbergh took off to cross the sea or die. The instant he landed, the Eifel Tower wireless flashed the news to Arlington. The War Department offices were notified first. At that moment a delegation of state health officers accompanied by Dr. Maurice Seymour, of Saskatchewan, President of the Conference of State and Provincial Health Authorities of North America, and led by the President-elect, Dr. Samuel Welch of Alabama, was making a plea in the War Department Office to General Lord, Director of the Budget, for additional funds to be used for health work in the flooded Mississippi valley. General Lord interrupted Dr. Welch, answered the telephone and repeated the thrilling message: "Lindbergh has landed in France."

Of those present, General Lord, Dr. Seymour and Dr. Welch have crossed the Great Divide. The others have a lasting and vivid mental picture of that incident. It emphasized the facts that distance is now measured by time alone; that natural barriers to disease importation no longer exist; and while new safeguards are needed the new potential hazards of disease spread are offset by easy and almost instantaneous communication between remote parts of the world. Today, October 27, regular commercial service between North America and Australia was begun by the American Telephone and

* Address of the President of the American Public Health Association, delivered at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 27, 1930.

Telegraph Company. The wire lines between New York and Sydney stretch over 14,000 miles and radio spans the seas.

Airplanes for investigation and wireless broadcasting of the facts concerning epidemics or threatened epidemics save time. These agencies are available for international and national, and in a few places, for state or provincial use, and should be universally adopted. They give the health authorities and allied agencies time to prepare a successful campaign for prevention or control. Their proper use by epidemiologists and other trained public health personnel will save lives, and prevent sickness and economic loss.

Reciprocal notification of epidemic diseases dates from 1879 when Dr. Charles N. Hewitt, Secretary of the Minnesota State Board of Health, Charter Member of this Association and its president in 1888, arranged for interchange of information between Minnesota, the province of Manitoba, the territory of Dakota and the states of Wisconsin and Iowa. Dr. Hewitt visited Canadian quarantine stations and, assisted by Dr. Frederick Montizambert, later Director General of Public Health of Canada and president of the American Public Health Association in 1891, entered into an agreement for reciprocal notification between Minnesota and the different Canadian ports which at that time did not report to each other but only to the Dominion headquarters office.

Cholera, plague and yellow fever led 12 European nations in 1851 to exchange information and adopt uniform preventive measures. These diseases were the primary concern at the Philadelphia Conference of 1857 called by the Health Boards of New York, Philadelphia, Boston, Baltimore and New Orleans, and attended by 73 delegates from 9 Atlantic states representing 26 boards of health, boards of trade and medical societies of the principal seaboard cities. This "Quarantine and Sanitary Conference" met in 1858, 1859 and 1860. In 1861 the Civil War interrupted its work.

The cholera epidemic of 1866 enabled the newly organized Metropolitan Board of Health to demonstrate its efficiency and paved the way for state legislation. The Massachusetts State Board of Health was established in 1869, the California Board in 1870, the Minnesota Board in 1872.

It is interesting to note that in 1872 when the American Public Health Association was organized Canada was represented by Dr. William Marsden of Quebec on the Committee on Permanent Organization, of which Dr. Stephen Smith was chairman; Massachusetts by Dr. George H. Derby, Secretary of the State Board of Health; the United States Army, the Navy and the Marine Hospital Service by medical

officers; while the other members represented Alabama, California, Connecticut, Illinois, Louisiana, Missouri, New York, Ohio, Pennsylvania, South Carolina, West Virginia, and the District of Columbia. Among the 67 members elected before the constitution was adopted were Dr. Phillip Carpenter of Montreal, Dr. Thomas M. Logan, Secretary California State Board of Health, Dr. Charles N. Hewitt, Secretary Minnesota State Board of Health, and Dr. George W. Peate, Health Officer of Galveston, Tex.

At the American Public Health Association meeting of 1875 a communication was read from the Secretary of the Association of Health Officers of the Lower Rhine requesting to be put in full fellowship with the Association for mutual interchange of publications. The American Public Health Association named ten delegates to attend the International Medical Congress at Philadelphia in 1876.

Thus coöperation and reciprocal notification in communicable diseases was begun here and abroad. Later, international organizations, official and nonofficial, relating to every phase of public health and welfare sprung up.

At least two Canadians helped organize the American Public Health Association in 1872, but Canada did not officially join until 1884. Five distinguished Canadian sanitarians have been presidents—Dr. Frederick Montizambert, 1891; Dr. Emmanuel Lachapelle, 1894; Dr. Peter H. Bryce, 1900; Dr. Robert M. Simpson, 1911; and Dr. Charles J. Hastings, 1918. Four times the standing and annually reiterated invitation from Canada to meet in one of her cities has been accepted—Toronto, 1886; Montreal, 1894; Ottawa, 1898; and Winnipeg, 1908. In 1889, Mexico, Cuba, Colombia and the Central American countries were invited to join. In 1890 the Superior Board of Health of Mexico sent delegates, and in 1902 Cuba entered the Association.

Dr. Eduardo Liceaga joined the Association in 1891, became president in 1896 and always took an active part in its affairs. To honor him the Association met in Mexico City in 1892 at the invitation of President Diaz, himself an Honorary Life Member. In his presidential address at Mexico City in 1892, Dr. Felix Formento said: "This is the first real International Health Congress on this side of the Atlantic." Dr. Domingo Orvananos, Delegate in 1890, was elected president at the second meeting held in Mexico City in 1906.

Dr. Carlos J. Finlay of Cuba, "the first to affirm the mode of transmission of yellow fever by means of the mosquito," was our president in 1904 and presided at the meeting in Havana in January, 1905. In 1911 the Association returned to Havana. Those fortunate members

who attended the meetings in Canada, Mexico, and Cuba, will certify that the facilities provided for the sessions and the quality of the reception cannot be excelled. Dr. Aristides Agramonte, whose name always will be associated with Finlay, Reed, Carroll, Lazear, Gorgas, and Guitéras in connection with yellow fever will address the Association at the final session Thursday evening, October 30.

Through the application of the results of the work of these great men, yellow fever—which for more than a century retarded our development, caused great loss of life, and forced upon infectible territories a system of drastic, highly individualized quarantines that cost hundreds of millions of dollars in delays to commerce—was first rationally dealt with from a quarantine standpoint, by the First Pan-American Sanitary Conference which met in Washington in 1902. Since that time this disease has been eradicated from all its strongholds in America save Brazil and—barring the possibility of its re-introduction by the rapid development of airplane traffic—ceases to be the dreaded scourge that it was in former times.

The Second Pan-American Conference, in 1905, adopted a treaty known as the Washington Convention which was a great step in advance in standardizing international quarantine procedures in America and abroad. The Washington Convention was the precursor of the present Pan-American Sanitary Code adopted in Havana in 1924 and since ratified by 17 American republics. This Code further unifies and standardizes our international procedures in the field of public health and obligates the signatory powers to report promptly all outbreaks of quarantinable diseases and the measures being taken for their control.

When the proposal to establish the Office International d'Hygiène Publique was accepted in 1907 by 12 European nations and the United States, Dr. Allan J. McLaughlin of the U. S. Public Health Service, president of the American Public Health Association in 1922, was the delegate of our government. This agency, set up at Paris in 1908, placed official coöperation on a permanent international basis and, through its relations with the Health Section of the League of Nations, information regarding outbreaks of quarantinable diseases is immediately available as they occur, practically throughout the entire world.

The directors of health from 21 American Republics will meet in Washington in 1931, and then attend the 46th annual Conference of State and Provincial Health Authorities of North America and the 28th annual Conference of State and Territorial Health Officers with the U. S. Public Health Service.

All Canadians who belong to the American Public Health Associa-

tion are members of the Canadian Public Health Association. They are as active and loyal in this Association as in their own. The same may be said of the members of the Conference of State and Provincial Health Authorities of North America; yet when the first Conference of State Health Officers was held at the time of the American Public Health Association meeting in 1884 some people feared that the Association would be weakened through withdrawal of representatives of state boards of health therefrom. The objectives of the Conference of State Health Officers are stated in the report of the Minnesota State Board of Health for 1883-1884 by Dr. Hewitt, who proposed the organization in 1879. They are very similar to those of the new International Association of Medical Health Officers about which there is now some apprehension.

While I venture no recommendation on matters of policy or of administration of the American Public Health Association, I believe that we should act with the courage of our convictions now and have faith in the future of the Association. A review of the history of our Association since its organization in 1872 shows that it has not yet attained the place its founders and sponsors marked for it.

In 1929 the Governing Council adopted a plan which places responsibility for administration upon the Executive Board and four standing committees: Fellowship and Membership, Meetings and Publications, Administrative Practice, and Research and Standards.

In June the Western Branch of the American Public Health Association met at Salt Lake City and ratified the Constitution and By-laws prepared by a committee appointed by Dr. W. C. Hassler and approved in principle by the Executive Board April 4, 1930. A program of great interest and value arranged by Dr. Hassler and Dr. William P. Shepard, Secretary, was carried out, and the enthusiastic appreciation, by the large assembly, of the hard work of Drs. Hassler and Shepard in building up the membership convinced everyone that the Western Branch will grow and be the means of speeding the progress of health work in the mountain and Pacific states and western Canada. Dr. H. M. Bracken, State Health Officer of Minnesota, 1897-1919, and since in Veterans' Bureau service and with the Los Angeles Health Department, now edits the Health Section of the *Western Hospital Magazine* which has been made the local organ for the Western Branch.

Reports of the work of the four standing committees and of the Salt Lake City meeting have been made to the Governing Council. A special committee named by the Chairman of the Executive Board at its last meeting reports to the Governing Council as follows:

THE AMERICAN PUBLIC HEALTH ASSOCIATION
ITS OBJECTIVES AND A PLEDGE OF THEIR ATTAINMENT

Our permanent objective is the effective control of preventable disease, and the security of health for all the people of our countries.

The first necessity to attain this objective is:

A full-time health service with trained personnel for every community and provision of adequate public funds for its support.

The first fruits of such organization and support of public health knowledge and resources will be:

1. Reduction of the maternal mortality rates so that the United States and Canada will be second to no nation in the safety of motherhood.
2. Securing normal growth of body and mind for children, and their training in the laws and personal practices of a healthy life.
3. Protection of life and limb and promotion of health for the working man and woman.
4. An adequate supply of safe milk for every community.
5. An adequate supply of pure water for every community.
6. Elimination of tuberculosis, malaria, hook-worm disease, typhoid fever, diphtheria and smallpox among the communicable diseases of which we have sufficient knowledge.

The American Public Health Association pledges to the health workers and to the people of our member nations vigorous coöperation in carrying these projects to a successful conclusion.

May I suggest that when you consider these reports you read again the address of President Fuller, and 3 other articles published in our JOURNAL:

1. Coöperation and Coördination of Voluntary Public Health Organizations, by Frederick R. Green. January, 1915.
2. Teamplay in Public Health, by George E. Vincent, President of the Rockefeller Foundation. January, 1919.
3. The American Public Health Association, Present, Past and Future, by W. S. Rankin. April, 1920.

If you do so, I think you will agree that while another year of experience is needed to determine whether the present plan is satisfactory, the early adoption of certain measures for the advancement of the Association is very desirable. The Association program for study and improvement of Administrative Practice has had a considerable and direct effect upon the organization of health work in the United States and Canada and in many countries abroad. Without the generous contributions from the Metropolitan and other life insurance companies, the Commonwealth Fund, and the Milbank Memorial Fund, the Association would not have been able to initiate this work or to provide for its continuance.

Certain recent events indicate that the present public health situation is better and its future brighter than ever. For example, President Hoover said in his message to Congress December 4, 1929:

The advance in scientific discovery as to disease and health imposes new considerations upon us. The Nation as a whole is vitally interested in the health of all the people; in protection from spread of contagious disease; in the relation of physical and mental disabilities to criminality; and in the economic and moral advancement which is fundamentally associated with sound body and mind. The organization of preventive measures and health education in its personal application should be as universal as public education. Its support is a proper burden upon the taxpayer. It cannot be organized with success, either in its sanitary or educational phases, except under public authority. It should be based upon local and state responsibility, but I consider that the Federal Government has an obligation of contribution to the establishment of such agencies.

In July, 1929, a White House Conference on Child Health and Protection assembled at President Hoover's request "to study the present status of the health and well-being of the children of the United States, to report what is being done, to recommend what ought to be done and how to do it." Members of this Association have worked earnestly as members of the White House Conference. Dr. William F. Snow of President Hoover's planning committee will outline the work during this meeting. In November a report will be made to the public. It will be followed by action for child health and protection. This Association will do its part.

Members of this Association are working on that important project known as a Study of the Costs of Medical Care, which concerns the people even more than the doctors, nurses and institutions engaged in the care of the sick. The facts already gathered indicate that changes of importance in the relation of medical service and the public health are imminent. The programs of the Rosenwald Fund, the Duke Foundation, and the Commonwealth Fund as they relate to community hospitals and to medical services may do much to influence these changes.

A most significant event of a different character but of world wide influence was the ceremony in Memorial Continental Hall, Washington, April 8, 1930, at the observance of the 80th birthday of Dr. William Henry Welch. Scientific gatherings throughout the world heard the President of the United States over the radio refer to Dr. Welch as "our greatest statesman in the field of public health," adding that "in organizing and directing research and application of medical knowledge on a wider field of prevention of diseases, he is among the preëminent few who deserve the title of statesman."

The passage in 1930 without opposition in Congress of certain acts

which this Association had advocated renewed our courage and faith in the future of public health work. The Honorable James S. Parker, Chairman, Committee on Interstate and Foreign Commerce, sponsored a bill that

. . . aims better to coördinate the public health activities of the government, especially of the Public Health Service; to give more specific statutory authority for certain activities of the Public Health Service and, to a limited extent, to broaden others; to improve its administrative procedure; to change the name, increase the personnel, and enlarge the functions of the Hygienic Laboratory Board and to authorize the establishment of new divisions in the Hygienic Laboratory; to increase the pay of officers of the Public Health Service; and to place the dental, sanitary engineer, and certain pharmacist personnel of the service upon the same commissioned basis as the medical officers.

Senator Joseph E. Ransdell, of Louisiana, was the author of legislation entitled—

An act to establish and operate a National Institute of Health, to create a system of fellowships in said institute, and to authorize the government to accept donations for use in ascertaining the cause, prevention and cure of disease affecting human beings and for other purposes.

Dr. George W. McCoy, who has so ably directed the Hygienic Laboratory, now becomes the director of the National Institute of Health. The Secretary of the Treasury has accepted from the Chemical Foundation, Inc., under the provision of the Ransdell Act a gift of \$100,000 for basic chemical research. Bona fide health authorities of states, counties and cities find the facilities of the National Institute of Health available for their study and instruction. Fellowships are provided for, either at the Institute itself or at other research institutes both in America and abroad. The Institute will be housed in a new building with adequate equipment.

Several federal departments publish reports and bulletins of great value to public health workers. The *Weekly Public Health Reports* give the latest information on prevalence of disease and contain special articles by the highest authorities on medical and sanitary science. The phrase which precedes, "Prevalence of Disease," is quoted daily—"No Health Department, state or local, can effectively prevent or control disease without knowledge of when, where and under what conditions cases are occurring." To this simple sentence Dr. John W. Trask, of the U. S. Public Health Service, boiled down his excellent article "Public Health Administration, Its Dependence upon Reports of Sickness." The bulletins of the Hygienic Laboratory are studied and treasured for reference. We thank the U. S. Public Health Service for the wide and free circulation of its publications.

The publications of the Army and Navy Medical departments are not so widely circulated. Public health workers who do not receive them are missing very valuable material. I refer to *The United States Naval Medical Bulletin* and to the special bulletins issued by the Army. Recently, *Army Medical Bulletin No. 23*, an excellent textbook on Military Preventive Medicine, was published under the direction of Major General Ireland, Surgeon General. The author, Major George C. Dunham of the Medical Field Service School, Carlisle Barracks, Pa., is well known in this Association.

There is a service of greatest importance of which I wish to speak. Unhampered by governmental restrictions, without a trace of selfish motive, with no desire for publicity, and firm in disapproval of propaganda, the International Health Division of the Rockefeller Foundation carries on a most effective world-wide campaign for the advancement of public health.

In the annual report of the Rockefeller Foundation for 1929 it is noted that the expenditures for all activities of the International Health Division, July 1, 1913, to December 31, 1929, amounted to \$39,815,421.50. Nearly \$3,000,000 was spent to aid Local Health Departments; over a million for State Health Services; \$1,200,000 for Field Service Expense, not pro-rated to Specific Budgets; \$2,737,000 for Public Health Education; more than \$800,000 for the Health Organization of the League of Nations; and nearly \$15,000,000 for the Investigation and Control of Specific Diseases.

Dr. Frederick F. Russell and his associates, Dr. John E. Ferrell, Dr. Victor G. Heiser, Dr. Hector H. Howard and Dr. Wilbur A. Sawyer, direct the work of the International Health Division. Members of its staff are scattered over the world, and wherever an emergency exists or there is an opportunity for field study and scientific research which may result in benefit to the public health, reduce sickness or save lives, the International Health Division will be found quietly carrying on its work. Many members of its staff have lost their lives in such endeavor. On June 30, 1929, a young scientist of great promise lost his life in the investigation of yellow fever. The members of this Association while glorying in the achievements of men of this character have the deepest sympathy for the members of his family and most sincerely regret his death. I refer to Dr. Theodore B. Hayne of Columbia, S. C., the son of Dr. James A. Hayne, State Health Officer.

You are well acquainted with what the International Health Division does and with its representatives in laboratory, office, and field work. Its splendid coöperation with governmental agencies—

national, state, provincial and local—is always most satisfactory. This is due to the policy of the Foundation which from its beginning has limited its health work to direct relations with governmental authorities—national, state or provincial and local. While campaigns have been directed against hookworm disease, malaria and yellow fever, the real purpose has been to use these control measures to build up official health organizations. The most notable example in the United States of the success of this policy is the continuance of the full-time health organizations established during the Mississippi flood of 1927. Eighty-five of the 100 counties where full-time units were established during the emergency have placed them on a permanent basis.

The Foundation in refusing to furnish aid to private health societies has no thought of questioning the value of these agencies. It has simply chosen a line of effort which seems to present permanent results in strengthening the official departments which have responsibility for protecting and promoting the public health.

The southern states have good reason to appreciate the aid of the International Health Board, and its predecessor, the Rockefeller Sanitary Commission, and also the coördinated activities of the U. S. Public Health Service.

Dr. George E. Vincent retired from the presidency of the Rockefeller Foundation December 31, 1929, and was succeeded by Dr. Max Mason. It would be appropriate for this Association to express its appreciation of the distinguished services of Dr. Vincent in the field of public health and to send its cordial greetings to Dr. Mason, whose scientific career indicates his high qualifications for this most responsible position of President of the Rockefeller Foundation.

At the present time there are at least three problems which require the fullest coöperation for their solution. An honored member of this Association, Dr. William Royal Stokes, lost his life, and a number of other research workers' lives were jeopardized through their work during the outbreak of psittacosis. Many official reports on the outbreaks in the United States and Canada have been published. Still the problem is not solved. The outbreak of typhus fever in 1930 presents some interesting and unsolved problems. Malaria has shown undue prevalence in certain northern states and invites careful epidemiological study. Rocky Mountain spotted fever is spreading. Two wood ticks that infest man and are able to carry spotted fever, *Dermacentor variabilis* and *Dermacentor occidentalis*, overlap the territory infested with *Dermacentor andersoni*, and the possibilities of spread through the agency of these ticks seem considerable.

Dr. William C. Hassler, President of the Western Branch of the American Public Health Association, and Dr. W. P. Shepard, Secretary, arranged a symposium on spotted fever for the meeting at Salt Lake City last June. An exhibit by Dr. R. R. Parker, of the U. S. Public Health Service, stationed at the research laboratory at Hamilton, Mont., attracted wide attention. Another exhibit by Dr. R. R. Spencer received the gold medal award at the Detroit meeting of the American Medical Association.

The present situation may be stated as follows: thirteen states are affected. Those most seriously involved are Idaho, Wyoming, Montana and Oregon, but the disease is endemic in California, Nevada, Utah, Colorado and Washington. It has spread into New Mexico, North Dakota, South Dakota and Nebraska. Epidemiological evidence indicates that in some of the recent cases in territory where *Dermacentor andersoni* is not found the disease has been transmitted by *Dermacentor variabilis*.

The Hamilton, Mont., laboratory during the past year has received 587 requests for spotted fever vaccine for use in Canada, California, Colorado, Idaho, Minnesota, Montana, Nevada, New Mexico, Oregon, South Dakota, Utah, Washington, and Wyoming.

The western states invaded have requested the Surgeon General of the U. S. Public Health Service to assume full control of spotted fever work by taking over the Hamilton laboratory, erected by the State of Montana, and extending the scope of the work as he may deem necessary. It is desired that spotted fever research, including tick parasite work, but not including control work such as rodent destruction, dipping of domestic animals and quarantine, should become the responsibility of the Service, while control work will be continued under the state authorities.

The Montana State Board of Entomology (Dr. W. F. Cogswell, Dr. W. J. Butler and Prof. R. A. Cooley), organized 18 years ago, has worked continuously on Rocky Mountain spotted fever and is now of the opinion that the use of parasites to destroy ticks is the most practical and most promising line of control work. This Board is already at work with the French tick parasite (*Ixodiphagus caucurtei*), but other parasites wherever they may occur should be found and imported. If one parasite is good, more would be better, and it is far from wise to rely on one alone. Prof. Cooley conducted research in Africa in 1928. He found two tick parasites new to science but the federal government would not permit him to bring them into the United States until their habits could be thoroughly studied in Africa. Effort is now being made to secure a fund to send Prof. Cooley back to

Africa to search for new tick parasites, study their habits, and prepare them for shipment to America, and particularly to study the two parasites discovered in 1928.

Successful research of this character would solve problems that puzzle epidemiologists and enable public health administrators to employ means for control and eradication of diseases affecting animals and man which now cause suffering, loss of life and great economic waste.

The ultimate success in world-wide control of preventable diseases and of the effort to improve the health of the people will be measured by the efficiency of local health units. Governmental co-operation and scientific research will become most effective when utilized in every community by trained public health personnel. To the promotion of coöperation and of research and to the organization of efficient local health units in every community the American Hygiene Health Association has pledged itself.

A Summary of the Records of Sixty-five Cases of Recoveries from Leprosy

A REPORT recently issued by the U. S. Public Health Service gives an interesting summary of the value of medical treatment for leprosy at the National Leprosarium which is conducted by the Service at Carville, La. More than 300 lepers, men, women and children, are under treatment there.

During the past 10 years, 65 lepers have been discharged from this hospital as apparently recovered from leprosy and no longer a menace to the public health. The average period of hospital care varied from 5 to 9 years. The shortest period of treatment was $1\frac{1}{2}$ years and the longest was 17 years. Fifty-five of these patients received crude chaulmoogra oil by mouth, and 16 of this group received no other medicine. Twelve received benzocaine-chaulmoogra oil by intramuscular injection, and 4 of these received no other medical treatment. Twenty-one received the ethyl esters of chaulmoogra oil by intramuscular injection, and 8 of these received no other medicine.

The basic treatment of leprosy is similar to that for tuberculosis, and all lepers at the National Leprosarium, no matter what medicines are given, follow a sanatorium regimen of food, fresh air and rest, almost identical with that prevailing in a tuberculosis hospital.

The Precise Evaluation of Light Therapy in Experimental Rickets*

JOHN W. M. BUNKER, PH. D., AND ROBERT S. HARRIS, S. B.

*Professor of Biochemistry and Physiology; and Research Associate; Massachusetts
Institute of Technology, Cambridge, Mass.*

THE use of ultra-violet light in prevention and cure of rickets is well known. The ultra-violet which is commonly believed to be most efficacious is between line 2,800 and line 3,100 Å. As far back as 1923

We had Weinstock¹ came to the conclusion that antirachitic radiations are limited to the zone 2,960–3,020. Others since that time have reported limits varying from these in some degree, but in the main it is today generally accepted that the antirachitic radiations are in the neighborhood of 3,000 Å.

The majority of the experimental data upon which are founded conclusions which have set these limits to the so-called "vital rays" have used as light sources mercury vapor arc lamps in quartz glass. The method in general was to employ filters of different selective absorption values which cut off short wave light up to a certain wave length, and in fewer cases cut off the visible end of the spectrum. One investigation by Sonne and Reckling² in 1927 made use of a quartz prism monochromator instead of filters. By this means it was possible to separate the lines of ultra-violet and to irradiate limited areas of white rat bodies with monochromatic ultra-violet light of different wave lengths between 2,200 and 3,560 Å. This would be an ideal way in which to investigate the problem of specific therapy from differing wave lengths if the volume and intensity of the illumination were sufficiently great. The size and cost of equipment to furnish a proper integration of ultra-violet light of sufficient intensity and dispersion completely to irradiate experimental animals is such that to date no such apparatus has been built.

A consideration of the various results obtained from the use of light filters may raise some doubt as to the validity of the general assumption that the therapeutic zone of light in successful treatment of

* Read before a Joint Session of the Food, Drugs and Nutrition and the Child Hygiene Sections of the American Public Health Association, at the Fifty-ninth Annual Meeting at Fort Worth, Texas, October 27, 1930.

rickets lies solely within the limits generally accepted. The principal reason for this doubt is the fact that experiments generally seem to have been planned without due regard for the fact that a "dose" of radiation energy is composed of two factors, intensity and duration. This makes necessary, for any valid comparison of different zones of light, not merely an equal time of exposure to different light bands but also the equalization of intensities of corresponding lines within the bands selected. It is admitted that occasional mention of energy measurement appears in the literature, but it is probably equally admissible that more exact work is required to support convincingly or combat the general conclusions which have been drawn. It is perhaps significant that the work, which from its published report seems to have included the most adequate precautions for securing a constant product of time and intensity, that of Sonne and Rekling, sets limits for antirachitic activity decidedly wider than the generally accepted limits.

In respect to visible light there seems to be no challenge of the theory that it is not effective in rickets therapy.

Attention has turned naturally to the question of the effect of infra-red radiations in rickets therapy since all ordinary sources of ultra-violet are at the same time sources of visible and of infra-red radiations. Hess and coworkers' reported in 1922 their finding that infra-red radiations interfere with antirachitic effect of ultra-violet, a conclusion which seems to have been corroborated by Clausen' in 1929. Reference will be made later to this point in respect to results obtained by the authors.

From the point of view of physics, it is recognized that light from any source is made up of lines differing from each other in frequency of vibration. Any photo-chemical effect is a function of frequency, intensity, and duration of exposure, since all these factors condition the input of energy by light. It is equally well established that the different lines of light from a quartz mercury arc vary greatly in individual intensities. It should be obvious that to compare the effect of a band of light containing lines of weak intensity with another band including corresponding lines of strong intensity, for the same length of time, may lead to erroneous conclusions as to the relative potency of the two bands in question.

For the above reasons, it was felt that there is needed an evaluation of different bands of light from the mercury arc lamp based upon comparisons wherein the intensity of light energy supplied should be equal in each case. Only from such a comparison can there be obtained a precise evaluation of light therapy in rickets.

In the attempt to secure such data at the Massachusetts Institute of Technology there were called in as collaborators Dr. Donald K. Stockbarger, radiations expert of the Department of Physics, and Dr. Edwin Wyman of the Children's Hospital in Boston, a recognized expert in successful application of radiations to rickets in children.

From the experiences of the authors in entering upon this, to them, new field of investigation there have arisen certain difficulties which it is felt may fall to the lot of any investigator in this field. From these experiences have arisen the suggested precautions which are offered in this paper for the benefit of others who are engaged in an attempt to execute precise experiments in this field of biophysics.

In the beginning of our work over 100 rats were carried through a period of 100 days in procedures gleaned from a study of the literature, before a single case of recognized rickets developed. The subsequent 700 or so animals used to date have behaved more satisfactorily.

We have come to the conclusion that it is possible to follow meticulously a classical method for developing rickets, and yet entirely miss the incidence of the disease. To prevent such disappointment we have outlined the following procedures which in our hands yield uniformly successful results.

The animals preferred are of Wistar stock, selected after comparison with stocks from other sources. The animals are bred in our own laboratory, using a diet for the mothers which is rather low in antirachitic factors, in so far as we know them, yet one which does not induce recognizable rickets in the parent or offspring. This diet was recommended by the Drug Manufacturers Association⁷ in 1930. It consists of—

	Per cent
Ground entire corn, yellow	34.0
Ground entire wheat	33.0
Klim whole milk powder	21.0
Old process linseed oil meal	7.0
Green alfalfa leaf flour	4.0
Calcium carbonate	0.5
Sodium chloride	0.5

As we shall report in detail elsewhere, it is important to grind the corn into meal and then store it at ordinary temperature, covered from dust, for 6 months before using. Market corn meal is apt to be deficient in growth factors. Some samples of whole corn contain so much anti-rachitic principle that freshly ground meal transmits too much of it for subsequent methodical onset of rickets. We have not found it necessary to sterilize the ingredients, and have felt that to do so impairs the necessary vitamin content of the diet.

For water supply, the drinking bottles have been filled with tap water and distilled water in comparison, and no difference in Cambridge, Mass., is noticeable. The addition of a trace of iodine to keep down algal growths in the bottles has not been demonstrated to have any effect, although the recent report of Kay *et al.*⁷ on the relation of thyroid activity and rickets should be kept in mind. All litters are reduced to six on the second day, and the animals are used for experimentation at age of 30 days, of weight 48 to 55 gm.

The rachitic diet of Steenbock No. 2965⁸ has proved satisfactory since we standardized our ground corn to an age of at least 6 months. Previous to such procedure, when using fresh corn purchased from a large variety of sources, results were irregular and failure to develop rickets was the rule rather than the desired result.

Animals are kept on this diet for 24 days, being subjected to daily irradiation 7 days a week, and are then subjected to post-mortem findings by X-ray and the line test as modified and described below.

The preparation of light sources for irradiation is time consuming and requires the services of the radiation measurements physical laboratory. Filters have been employed for lack of the huge quartz monochromator which would of course be the ideal instrument.

A characteristic of light filters, not realized by some, is that they do not cut off sharply in their absorption. It is also unfortunate that two filter mediums which differ in the point of practical cut-off vary also in the relative intensity transmission of lines to which each is transparent. It is possible to say of any filter that it cuts off transmission of all radiations below a certain wave length, but it is equally true and unfortunate that the change from transmission to absorption is a sloping curve and not an abrupt line. We have found no common filters having a narrowly restricted zone of transmission in terms of wave length of sufficient relative transmission to be practical.

In our work, filters have been prepared of special glass and glass plus chemical solutions which cut off lines of shorter wave length than 2,650, and also successively increasing increments from the infra-red end of the spectrum. Since for each filter the relative transmission of lines common to all is variable, they have been standardized in sets to a common intensity at first one line and then another in the zone around 3,000. This has meant that through each filter the total energy has varied, but the energy at a particular line has been common to a whole set. Usually four filters have been used in this way at one time.

For a light source, Cooper Hewitt mercury vapor lamps have been employed each in a set-up standardized as to voltage, and at such a

distance from the animal bench that each delivers the same total energy from the bare arc. Each lamp was run for 100 hours to give the quartz the necessary preliminary aging. Each lamp is operated for the same length of time each day and all are frequently checked for uniform energy transmission.

A standardized dosage with the complete arc has been worked out which every time protects each of the eight control rats of an experiment against rickets.

Our diagnosis of rickets under these standard conditions is always by X-ray and line test on the femur bones of animals killed after 24 days. Macroscopic evidence of rickets has not been reliable in our experience. The line test is carried out in the classical manner with the exception that the split bones are held over night in the icebox in 10 per cent formalin and then after washing and the usual treatment with acetone and silver nitrate are exposed to ultra-violet light instead of the light of "a strong incandescent lamp." More positive demarcation of "lines" results.

In the X-ray pictures of the same bones, taken previously, a low voltage with slow development has resulted in formation of sharper shadows, more convincing to the examiner.

As the result of two years of continuous work, using upwards of 800 animals and employing the above precautions, but one repeatedly consistent result has been obtained. All animals subjected to the standard irradiation of measured intensity under the bare arc have been protected against rickets. In every other group excluding first infra-red, then visible light, then portions of the spectrum down as far as 3,300, with intensities equal at lines 3,000, or at 2,804, there has been some protection and some failure in protection. Single experiments can be selected from the list to prove that the vital band is restricted to a narrow zone and others to show equally convincingly that the therapeutic zone is wider. The unreliability of these experiments was demonstrated only by repeated checks and repetitions. Usually four repetitions of a given experiment were sufficient to show irregularities in results. Whether check experiments were carried out simultaneously on a given batch of animals or whether they were run successively under standardized conditions with the same identical set-up, the variations have occurred; yet all the while the control experiments with the bare arcs have been monotonously successful in protecting the animals, the intensity of the bare arc in the region of the so-called "vital band" always being equalized to the intensity of the same region of the filtered light.

In respect to the infra-red effects, our findings must be considered

tentative until several more repetitions of this work have been carried through. At present it appears that, whereas the bare arc unfiltered gives uniform protection, the same dosage if immediately followed by a certain amount of additional infra-red radiation lends protection in only about one-third of the animals. If, on the other hand, the infra-red treatment precedes the therapeutic dose of light from the bare arc, the protection is extended to two-thirds of the animals. Infra-red alone confers no protection. Moreover, in the case of a light filter which cuts off the short-wave middle ultra-violet but transmits in the zone of 3,000 with equal intensity to bare arc exposure, and transmits the remainder of the spectrum with varying intensities, there was at best 23 per cent protection if infra-red was a component of the total energy, but 40 per cent protection if the infra-red was removed by water. This appears to confirm and to amplify the findings of Hess and of Clausen.

CONCLUSIONS

In precise evaluation of light therapy in experimental rickets it is necessary to exercise meticulous care in standardizing all procedures in respect to breeding and care of animals.

In the matter of diet, one factor which may be variable to a bothersome degree is the amount of antirachitic factor in freshly ground yellow corn, which variable can be reduced by definite aging of the corn meal before use.

In comparison of different light zones, the characteristics and limitations of selectively absorbing filters must be understood, and compensations therefor be introduced into the set-up.

Numerous repetitions of each set of experiments, with controls common to all compared conditions, must be carried out.

In the light of results obtained, it is felt that the rather general belief that antirachitic effect of light in rickets prevention in white rats is confined to the zone of ultra-violet in the neighborhood of 3,000 Å. and that other parts of the spectrum from the mercury arc lamp are without contributory effect, is a belief that is not adequately supported by experimental evidence.

It is, in our opinion, still a possibility that the future will show that radiations longer or shorter in wave length than those of the alleged "vital band" of ultra-violet may assist in the biochemical processes of rickets therapy.

Evolving a Health Department

ENNION G. WILLIAMS, M. D.

State Health Commissioner, Richmond, Va.

THE best way to secure a profitable discussion of health work as a governmental function is to take the actual experience of a health department, describing its problems and its phases of evolution.

Although Hippocrates warns us, "Experience is fallacious," I sympathize with Patrick Henry who said that he had "no other guide"; and I might add another maxim: "By knowledge is a house builded and by wisdom is it established."

In 1908, the General Assembly of Virginia, with the cordial approval of the governor, reorganized the State Board of Health and actually created a health department for the state. Prior to that year, health measures were limited to activity in the presence of large epidemics, chiefly smallpox, and the issuance of occasional literature.

Preventive medicine is probably still in its infancy; but it has made remarkable progress in popular esteem during the last quarter of a century, and much has been added to its strength. The vastly increased state and federal appropriations of today are a tribute to the intelligence of the people who are in annually increasing numbers becoming convinced that many of our diseases can be and should be prevented.

It may serve to show how intelligently our legislators viewed health work if I give the authorized personnel of the new department created in 1908. It was to consist of a commissioner, an assistant commissioner and a bacteriologist; but there was no doubt as to the intent of the law makers. They wished to insure the utilization of the knowledge then available, and they prescribed that the commissioner "be versed in bacteriology and sanitary science," that the assistant commissioner have similar qualifications, and that the bacteriologist be "competent." To carry out the provisions of the new law, and to make the work effective, an appropriation of \$40,000 annually was provided.

Then came the duty of formulating plans and policies for the profitable expenditure of the appropriation. The new commissioner had no "lamp of experience"; so he sought to study by the lamps of others. He visited a number of other state health departments—

there were not many of them at that time—but he found no standards. He returned to Virginia feeling sure the work was in a pioneer stage and that the wisest course would be to begin by adapting to the chief needs of his state such knowledge as was available.

Even this elementary conclusion had its qualifications. A point at once to be established was—the field of the health department. Obviously it should not engage in curative medicine for that was an individual, rather than a public, concern; but there were other fields less clearly marked. The state was then, as it is now, recognizing as a public duty certain medical activities, such as the support of medical colleges, the licensing of medical practitioners, the free treatment of certain indigent patients at state supported hospitals, the maintaining of hospitals for the insane and schools for the deaf and blind.

We decided that none of these activities should properly fall within the purview of public health endeavor, even though some of them might have a distinctly public viewpoint; but there were some other activities discussed later that could not be so rigidly excluded.

Our first principle was: It is the duty of the health department to work for the benefit of the general population rather than for the benefit of any individual.

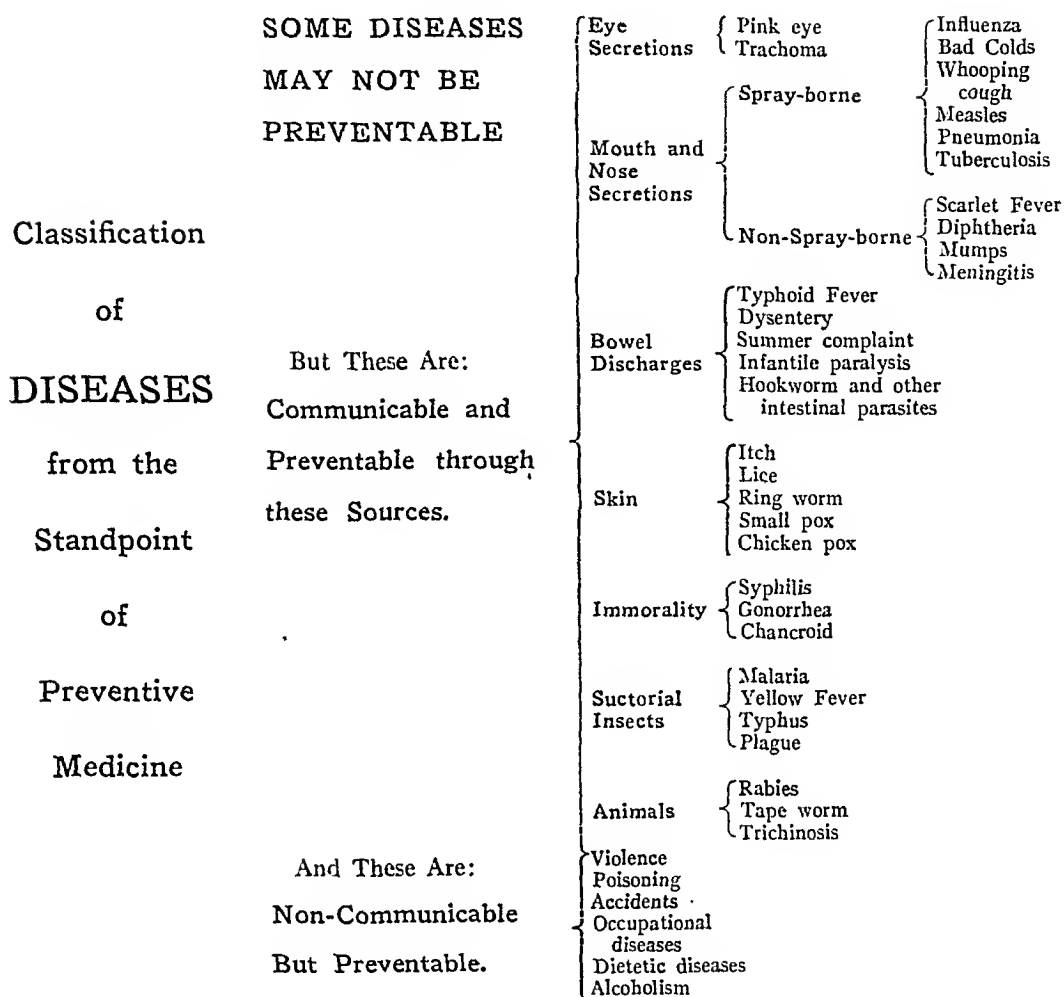

At once this marked the public health field as separate and distinct from the domain of the private practitioner, whose first duty is to his patient; but later we found that it was far easier to make such a distinction than it was to adhere to it rigidly. We found that we would have to modify our first principle, and whether we have been wise or unwise will be left for discussion.

We classified our chief undertakings as Education, Epidemiology and Laboratory. We sought to instruct the people, to tell them in simple language how single diseases and groups of diseases are transmitted and how the spread of such diseases might be prevented. A chart we used effectively to explain how diseases are transmitted is shown in Figure I.

As a logical complement of education and epidemiology in the pioneer stage, a laboratory is an obvious necessity. It enlists the interest of the practitioner, encourages him to do scientific work, and aids the department in securing prompt reports of communicable diseases. In that workshop, we have adhered to our first principle, we have limited our examinations to specimens for the diagnosis of communicable diseases, and do not examine for non-communicable diseases. Examinations of water samples to determine safety for drinking purposes are made.

Under our law, the Agricultural Department has supervision of

FIGURE I

milk and other foods. We have made only one departure from this principle made necessary by a development discussed later.

Our great handicap at the beginning was that we did not know where diseases were occurring. We had no bureau of vital statistics to give us information as to deaths; we had no reports of cases from doctors. Promptly we organized a system of monthly reporting by sending to each doctor in the state every month a letter in which we called attention to the law requiring monthly reports, and enclosed a return postal card on which were printed the names of the communicable diseases we wished reported.

In this way, we ascertained for the first time the relative prevalence of communicable diseases in the state. These reports were from the first valuable because we could locate epidemics, and make epidemiological studies that decided our original line of chief endeavor.

No special study or reports were needed to show that tuberculosis

was a major problem; and the law creating the new health department instructed the board to establish a sanatorium for the treatment of tuberculosis. It might seem that this was in conflict with our principle of considering the public rather than the individual; but our construction of the mandate given us was in line with public health policy. Tuberculosis was a communicable disease and every victim was a potential focus of infection.

With limited funds we decided that we would, so far as possible, restrict patients admitted to the sanatorium to the minimal or moderately advanced classes who would, it is true, be personally benefitted by their stay but who would also be made into public health agencies after leaving the sanatorium. In other words, they would be taught to protect others against any respiratory diseases which they might have, and they would be object lessons to their communities in teaching through example the means of avoiding the transmission of the germs. Furthermore, minimal and moderately advanced cases, mingling more with others, are greater public menaces. Also, the advanced case would be less benefitted and require longer stay at the sanatorium.

FIGURE II

Annual Death Rate from Typhoid, State of Virginia

Our first discovery was that the intestinal diseases, mainly typhoid, were responsible for an undue proportion of sickness in towns and cities—generally throughout the state but especially in the more thickly settled communities. Upon presentation of these facts, the next General Assembly authorized us to employ a sanitary engineer and to begin the systematic protection of municipal and all other water systems supplying the needs of as many as 25 people. This engineer was also charged with the promotion of public sewer systems. Thus began the Bureau of Sanitary Engineering and the state supervision of all public water supplies.

RURAL SANITATION

In 1912, The Rockefeller Foundation helped to finance a hookworm study in several southern states, including Virginia. Our monthly reports from rural doctors had revealed the widespread prevalence of typhoid fever. The hookworm study showed in many counties an average of 20 per cent infection. These facts suggested the desirability of an accurate sanitary survey of rural homes, of sufficient size to serve as a fair guide to general conditions. So we surveyed 12,000 homes scattered throughout the state and found that 36 per cent of them had no sewage disposal facilities of any sort, and only 0.3 per cent had sanitary sewage disposal. Surely this was sufficient explanation of our typhoid, diarrhea, dysentery, hookworm and other intestinal parasites.

We had already begun the protection of municipal water supplies and the establishment of more municipal sewer systems, and now turned our attention toward the creation of rural sanitation. We established a division of rural sanitation. All public water supplies and public sewer systems have been left under the direction of our sanitary engineering bureau, but private supplies and sewage disposal are under the division of rural sanitation.

SANITATION OFFICER PLAN

For encouraging localities to undertake systematic sanitation, we devised a plan in coöperation with the U. S. Public Health Service.

Any county that desires to employ a sanitation officer must appropriate \$1,500 annually. To that sum we add \$1,000 and furnish a well trained man to do the work. As his value increases and becomes evident, the counties usually add to their appropriations and, to a certain limit, we increase ours proportionately. This worker, who gets a salary varying from \$1,500 as a minimum to \$2,400 as a maximum, is not a medically trained man but a layman, carefully trained

to do two things—show the people how to construct privies in which sewage will not be accessible to flies or endanger the water supply, and how to protect the water supplies from the contamination of human filth. We find that this work becomes increasingly popular as the years pass; less urging is needed to induce counties to engage sanitation officers; and their work frequently leads to the adoption of a generalized health department.

CHILD HEALTH

In 1916, we were asked to survey a rural county to determine the condition of the children. We were rather surprised to discover the large proportion of those with troubles that interfered with their normal mental and physical growth. Before we had reached any conclusion as to methods for solving this problem, the nation was plunged into war. Then the draft boards revealed the alarmingly large number of unfit. We were almost as bad as England in that respect, and conditions in England caused Lloyd George to say that it was impossible to build a Class A Empire out of Class C citizens.

As a natural corollary to our survey and the disclosures of the draft board, we had to begin work for the correction of defects of childhood. This we have been able to do most effectively and without any conflict with the medical profession.

The General Assembly of 1918 passed a law which makes it a prerequisite for obtaining a permit to teach that the applicant must have successfully passed an examination on physical education and physical inspection of school children, on the control of communicable diseases and school hygiene. The course of study is prepared jointly by the Superintendent of Public Instruction and the State Health Commissioner, and is now taught in all teacher training schools and colleges throughout the state and by a correspondence course conducted by the Health Department.

It has been a great factor in promoting popular health education to have over 16,000 teachers scattered through the state, each with some definite knowledge in elementary health matters, each knowing the simple facts in relation to the cause and prevention of communicable disease, each being able to recognize simple physical defects or departures from normality. The inspection work demanded of the teacher is a process which can be undertaken by anyone of good intelligence, if slightly trained. We require only inspection that will determine over or under weight, faulty vision, poor hearing, teeth requiring attention, and such obvious defects of nose or throat as make a child a mouth-breather or victim of frequent colds. This constitutes our 5-point program.

In the work of inspection, the nurse may assist if requested; but her main function is to establish contacts and to secure, if possible, the correction of the defects found. When the parents can pay for corrections, it is usually an easy matter; but when evident poverty prevents, the problem becomes difficult. In such cases, there is usually coöperation between the local health authorities, school authorities, doctors, and the population. The State Health Department will not assume any responsibility for the conduct of curative clinics; but will permit its local representatives to assist in the conduct of such clinics as are operated with the approval of the local health authorities and medical profession and in accordance with the plans approved by the State Medical Society.

For a plan to secure the corrections of dental defects, we requested aid from the State Dental Society. It appointed a committee; and a former president of the society gave up his practice for 6 months during which time he made a careful study of the dental needs of the rural sections, visiting nearly every dentist in the state. He formulated a plan which was unanimously approved by the society, and for 10 years it has been in successful operation. We have a director of oral hygiene who supervises the work and who employs 14 or 15 dentists to look after school children and even younger ones. An extremely moderate charge is made to cover actual costs. The great majority of the children pay though some are unable. If there should be a deficit from the clinic, the state and the locality share equally in the loss.

Few dentists, if any, object to this procedure. They frankly admit that our school clinics are advantageous to them through increasing their adult practice; and furthermore feel that children who have been taught the necessity of care for the teeth are not apt to forget that lesson when they grow up.

It certainly would seem possible for the medical profession similarly to adopt, in coöperation with public health authorities, a program that would encourage medical attention for children and thereby build up a desire for life extension that would cover all ages.

MATERNITY AND INFANCY

This problem of child health and welfare was closely associated with another subject, the health and welfare of mothers and infants. In 1912, the General Assembly authorized a bureau of vital statistics, and from the start it was evident that our maternal and infant death rates were unduly high. It seemed to us that these might be lowered by the use of public health nurses, registered nurses who had graduated from accredited hospitals and who in addition had received spe-

cial training in public health work. So, to solve these problems, a bureau of public health nursing and child welfare was established in the health department.

It was evident that mothers needed instruction in the care of themselves and their infants. This could be given by the visiting public health nurse, but her usefulness is necessarily limited. A correspondence course for mothers was begun. We were fortunate in securing as director of this course the wife of a doctor—a mother, and a graduate nurse with public health experience. A course of 12 lessons was planned with the help and approval of members of a committee of the State Medical Society. The popularity of the course is attested by the fact that 2,589 have taken it in 7 years.

But how were we to function without interfering with the private practitioner? We did not want to depart from our principle of limiting our viewpoint to the public versus the individual notwithstanding the definite need for the service; so we asked the organized profession in Virginia, as represented by the Medical Society of Virginia, to appoint committees to coöperate with us in formulating plans and in conducting the work. Later the federal government adopted the Sheppard-Towner plan of aid to states engaging in work for mothers and infants.

Strictly speaking, this as a function of the public health department is debatable, however desirable and popular it may be. However, in states preponderantly rural, especially in those presenting topographical difficulties of intercommunication and economic stresses, the work is justifiable especially when it is so conducted as not to trench upon the legitimate domain of private medicine.

As part of the maternity work, we endeavor to exercise control over midwives. It is not so effective as we would wish, but it is becoming more so. When we began supervision and instruction of these women there were about 9,000 midwives in the state; there are now less than half that number practising. We have a state director of midwifery instruction, and she personally or through nurses has trained and given instruction to classes in 85 counties. Local midwives are required to attend those classes; and the ignorant ones soon drop out. We have not endeavored to fix standards for midwives. They constitute a problem which we do not feel entirely competent to solve. Our doctors admit the necessity for them while deploring their lack of training. We, therefore, have followed the advice of the profession and confined our eliminations to the glaringly unfit.

There is one laboratory operation which could not by itself be regarded as a public health endeavor, yet we have to undertake it as part of a program. Having adopted a plan for maternity work. we

have had to consider prenatal conditions, and do urinalyses when samples are sent by our nurses for midwife cases. This enables the nurses to assure medical care for those mothers who need it, and many who might have risked their lives with midwives have, by this method, been placed in time under the care of physicians.

FIGURE III

Annual Death Rate from Tuberculosis, All Forms, State of Virginia

TUBERCULOSIS CONTROL

I have mentioned the establishment of a tuberculosis sanatorium, during our first biennium. We now have 3 of these institutions, 2 for white people and 1 for colored. We have still further extended our work for the tuberculous. Years ago it became obvious that only a small proportion of the tuberculous in Virginia could be provided with sanatorium care, so we inaugurated a system of case finding clinics and out-patient service. Again we were assured sympathetic coöperation on the part of the medical profession.

We have two traveling clinics, each consisting of 1 doctor and 4 nurses. Each doctor spends 1 week in a county and each nurse spends 4 weeks. The nurses visit all doctors in the county, find contacts, advertise and arrange the clinics, assist the clinician while he is in the county, and after the clinic it is the job of the nurse to induce all positive or suspected cases to go to their family physicians. All local

doctors are invited to take part in the clinic. The findings of the clinician are reported to the family physician.

Although the Medical Society of Virginia approved our method of conducting case finding clinics, we never go into a community unless we have previously secured the approval of the local doctors. At first, some of these demurred, taking the ground that our clinics were a reflection on their skill in diagnosis; but, as patients not under a doctor's care began to visit the doctors, this opposition waned and the clinic service came to be most welcome. Doctors in some localities have taken such interest in the work that we have been able to leave clinics in their hands. That would be an ideal for the whole state if it could be realized.

VENEREAL DISEASE

During wartime, the federal government began a determined fight against the venereal diseases; conducted a number of free clinics for treatment; and aided financially in law enforcement and educational measures. When it withdrew its allotment of funds, these local free clinics closed and law enforcement ended so far as the state's responsibility was concerned. Recognizing venereal diseases as matters of public health interest by reason of their communicability, we felt that educational propaganda would be justified. This has consisted of lectures and the distribution of literature on sex education.

FIGURE IV

Annual Death Rate from Malaria, State of Virginia

Even in this limited field we were not entirely satisfied that we were justified; so we addressed letters to all college presidents in Virginia and to all division superintendents of schools asking for opinions as to the value of the work as conducted, and whether, if worth while, it should be continued under the Health Department or the Department of Education. So many answers indicated a preference for the Department of Education, and this so coincided with our views, that we asked the General Assembly of 1930 to reduce its appropriation to us to be used for this work.

A large part of our laboratory examinations has, however, to do with venereal diseases. We do more than 30,000 Wassermanns each year and a large number of examinations for gonorrhea. This work probably requires no excuse as a public health activity, though at one time private laboratories did object. The subject was discussed at an annual meeting of the State Medical Society and, by a practically unanimous vote, the society requested us to continue this service to the doctors of the state.

MALARIA

We have naturally developed our epidemiological work as the years have passed and have undertaken some definite campaigns as a consequence. For instance, for several years we made a strenuous

FIGURE V

Annual Death Rate from Diphtheria, State of Virginia

campaign against malaria in sections which showed a continuing and large prevalence. Malaria has virtually disappeared as a cause of death. To what extent that has been due to our efforts or to influences unrecognized by us, I do not presume to say; but the reason for intensive and strenuous work having ceased, we are not now paying as much attention to malaria. We have many notable instances where a long standing and extensive prevalence of severe malaria disappeared under the strenuous, well directed anti-malaria measures conducted by the United States, state and local agencies.

DIPHTHERIA

Three years ago we immunized about 200,000 children; or, to be more exact, we gave toxin-antitoxin to that number. Our death rate from diphtheria made an immediate and most satisfactory decline in face of a higher rate that year for the nation as a whole. Since then we have more nearly approximated the national curve, which indicates a necessity for a second campaign.

OPPORTUNISTS

I mention these instances to show that we have been opportunists, doing the work which seemed most timely and necessary, dropping special campaigns when they seemed to have accomplished their purposes, returning to them if later it should seem necessary. We may again have to work intensively against malaria. Although our succeeding General Assemblies have been increasingly appreciative of health work, and our appropriations have grown from the modest first appropriation of \$40,000 to somewhat over \$1,250,000 for the biennium beginning July 1, 1930, we still have to consider carefully our expenditures in the light of immediate needs.

Virginia, following the lead of the federal government, placed in the Department of Agriculture the supervision of dairies and food. This arrangement was in force before the State Health Department was recognized in 1908. While in principle I believe a state health department should have supervision of dairy and food products as in cities, in practical operation we have had fine coöperation with the officials of this department and I believe the public health is efficiently safeguarded by the present arrangement.

In 1927, the sanitation of shellfish handling and production was placed with the health department. A floating laboratory is maintained for testing the pollution of growing beds, inspection is maintained of shucking plants and the personal hygiene of the workers. Furthermore, there is steady effort made to bring about sanitation in

the whole oyster producing area that all the filth-borne diseases will disappear.

CONCLUSION

I have given in bald outline the major steps in the development of health work in my state. In conclusion, I ask you to consider the activities of health work for which public funds are appropriated. These may be roughly divided into:

Prevention of disease
Promotion of health
Cure of disease

With the last we are not concerned. We are directly concerned with the first, and we have a considerable interest in the second, the responsibility for which we divide with the medical profession.

To illustrate our interest in the first division, we might define the subject as embracing health education; sanitation, which would include excreta disposal, protection of water supplies, the guarding of milk and foods, the control of flies, mosquitoes and other germ-carrying insects; personal prophylaxis, such as vaccination against small-pox, diphtheria, typhoid or any disease for which we may find a reasonably successful immunizing agent; epidemiological work for either study or control; laboratory; and vital statistics. Surely no one can dispute our interest in these subjects and our right to work in these fields.

Promotion of health I take to include maternity and infancy welfare, instruction and practice in physical inspection of school children, school hygiene and correctional clinics. I am not including in this list tuberculosis clinics as conducted by us—they are in effect helping in diagnosis of communicable disease—but I would include periodic examination of adults, not as something to be undertaken by us but as something to be encouraged by all health workers. So far as other divisions are concerned, I have told how they operate in Virginia; and they are open for discussion.

It seems to me that under the classification, "Promotion of Health," we find our twilight zone. Any effort in these lines may easily become obnoxious to the profession; and we cannot hope to gain in popularity, esteem or results, if we align the medical profession against us. All activities in this classification should be developed with the approval of the medical profession and carried on with the coöperation of the doctors. It is always well to consider the undeniable fact that, when we plan to enlarge our fields of usefulness,

we should be sure that, in striving for wider areas, we do not risk the area we occupy.

When developing full-time health service in rural sections, we recommend, as the first step, the employment of a sanitation officer, whose entire time shall be devoted to the securing of sanitation and to the protection of individual water supplies. Our second recommendation is the employment of a public health nurse, who serves principally in maternity instruction, in teaching infant care and looking after children in the schools. We do not recommend a full-time medical health officer until these lay workers have been assured, for unless he has these workers to aid him he is not apt to justify the cost of his employment; and, so we insist, that when a medical health officer is employed, he shall have these lay assistants.

Investigation of Infant Mortality in Brazil

A REPORT on the investigation of infant mortality in Brazil, made under the auspices of the Section of Hygiene of the League of Nations, was recently published.

The investigation was made in 8 districts, some urban, others rural, and was concerned with 7,379 live births, mostly in poor families. The infant mortality rate varied according to the district from 96 to 201 per 1,000 live births. The lowest rate, 96, was obtained in a prosperous town, where living conditions and sanitation were satisfactory; there was also in that town a health center maintained by the Government and doing prenatal and child welfare work, and a clinic for venereal diseases. The highest infant mortality rate was obtained in a rural district where the inhabitants were very poor, and the conditions of sanitation were very unsatisfactory.

More than one-half of the children studied died before the end of 3 months, and almost one-third of all deaths were caused by diseases due to nutritional disturbances. It was found that while 40 per cent of the children were fed at the breast, of those who died of nutritional disturbances only about 13 per cent were so fed.

It was also noted that the care given to the mothers at childbirth and to the child improved with the improvement of the economic situation of the family.—*Archivos de Hygiene*, Publicação do Departamento Nacional de Saude Publica, Rio de Janeiro, 1930, No. 2, p. 61.

Incidence of Partial Paralysis*

E. L. BISHOP, M. D., F. A. P. H. A., AND H. C. STEWART, M. D.

*Commissioner and Epidemiologist, Tennessee Department of Public Health,
Nashville, Tenn.*

IN March the attention of the Tennessee State Department of Public Health was called to the occurrence of a number of cases of a condition which, for want of a better term, has been called "partial paralysis." A number of other terms have also been applied such as "peripheral polyneuritis," "toxic polyneuritis," and "Jamaica ginger paralysis." Terms in common usage have been: "Jake leg," "Jake foot," "Jake hop," and "Jake paralysis."

So far as our information goes, cases have been reported in greater numbers in the southern states, especially Mississippi, Alabama, Georgia, Oklahoma, Tennessee and Kentucky.

The experience with regard to the cases occurring in Tennessee is the basis for this paper. There have been gathered more or less complete histories from 208 cases. This in all probability does not indicate the true extent of the condition, as many cases have occurred without being seen by any physician. Information gathered in the areas of greatest prevalence in Tennessee leads to the assumption that only about two-thirds of the cases have been reported. Of the 208 cases, 185 were from 4 counties, Washington, Carter, Sullivan and Unicoi, which are contiguous and located in the extreme northeastern section of the state, the greatest number being from the 2 counties first mentioned—Washington with 120 cases, and Carter with 52 cases. However, scattered cases were reported from 8 other counties.

SYMPTOMS

The first thing noted in the majority of cases was weakness of the feet. This was followed by soreness in the calves of the legs, and tenderness over the calf muscles on pressure. In a few instances a history of an antecedent acute infection was elicited, such as sore throat, coryza, or symptoms suggesting an infectious onset such as chill, fever, general body aching, and headache. This appears to have been coincidental. There occurred in some cases premonitory symptoms of soreness in or quivering of the calf muscles.

* Read before the Epidemiology Section of the American Public Health Association, at the Fifty-ninth Annual Meeting at Fort Worth, Tex., October 29, 1930.

Paralysis of the lower extremities reached its maximum extent in from 2 days to 1 week. Those patients showing involvement of the fingers, hands or wrists, stated that these members did not develop weakness until from 3 days to 1 week after the time of onset of weakness in the feet.

When questioned, the patients complained of coldness of the affected extremities, and many complained of numbness and tingling. The latter symptoms were frequently transient, existing only for 24 to 48 hours. Only 1 complained of anesthesia over the feet. There were no cranial nerve symptoms in any patient, and no history of sphincter disturbance.

NEUROLOGICAL EXAMINATION

The following is quoted from reports of Dr. Hugh J. Morgan, Professor of Clinical Medicine, Vanderbilt University, opportunity having been afforded him to see and examine some 15 cases.

Gait—The gait is the typical steppage gait of peripheral neuritis with dragging toes and flail-like tapping of the feet. Patients use canes or crutches and constantly hold to some object, walking from wall to chair, to bed, etc.

Trophic Disturbances—The affected members are invariably cold and wet with perspiration. Cyanosis of the affected members was present in a few, and 1 girl showed slight edema of the affected feet. This same patient showed over the shins and feet a diffuse erythema with a few papular erythematous lesions interpreted as trophic. All complained that the affected members were cold, and this, together with the sweating, was the most striking vasomotor change.

Motor Changes—Complete or partial paralysis of the muscles of the flexors and extensors of the toes and feet were the most constant findings. Dorsal flexion of the toes and of the feet was constantly impaired. In some cases plantar flexion of the toes and feet was not completely absent, even though complete paralysis of the opposing muscles was present. Weakness in the flexor and extensor muscles of the leg was seen, but in fewer numbers, and no complete paralysis of these groups of muscles was noted. Two cases showed involvement of the thigh muscles.

In the upper extremities the first muscles affected seemed to be those of the thumb and first finger, although complete extensor paralysis of the fingers was common. Extensor paralysis or weakness of the wrists was also almost invariably present when the upper extremities showed any involvement at all. Patients were also seen who showed involvement of the fingers and wrists, although these were less numerous. About half of the patients showed some involvement of the upper extremities, whereas all of them showed lower extremity involvement.

Motor cranial nerve involvement, or involvement of the trunk muscles, was not observed in any patient.

Sensory Changes—Mild subjective sensory disturbances were complained of by many patients. Demonstrable sensory changes were noted in relatively few. Two patients were seen showing a stocking type of anesthesia over the lower extremities. One of the Vanderbilt Hospital cases has shown the glove type of anesthesia of the upper extremities.

Most of the patients complained of tenderness on pressure over the calf muscles. No definite tumefactions were felt along the course of any of the peripheral nerves.

Reflexes—Absent ankle jerks was a constant finding. Not a single case showing absent knee jerks or absence of the deep reflexes of the upper extremities was seen. The cremasterics and abdominal reflexes showed no constant change. In cases closely questioned there was no history of any disturbance of visceral reflexes (bladder, rectum).

Cranial Nerves—A complete examination of the cranial nerves (including ophthalmoscopic examination) was made in 9 cases with negative findings.

Clinical descriptions and reports of cases in other areas are to be found in publications by C. R. Bennett,¹ and S. Harris.²

TENNESSEE EXPERIENCE

The State Department of Public Health was first advised of the development of these cases on March 8, 1930. Staff members were immediately sent to assist the local full-time health officers in an investigation. Epidemiological case cards were completed for all cases that could be located. It was immediately apparent that a decidedly strange age and sex distribution had occurred when comparison was made with the conditions of a communicable nature. No case had occurred under the age of 15 years; 79 per cent of cases were in the age group 20 to 45 years. Of the total 85 per cent were males. Such a distribution could not be compared with any infectious condition with which previous experience had been had. Such a distribution might occur as a result of exposure of certain occupational groups to the causative agent.

Many types of occupation were represented, as follows: 67 were laborers of various kinds, 23 of these being in artificial silk manufacturing plants, this being the main industry of Elizabethton; 19 were clerks; 17 were classed as housewives; 14 were merchants; 11 were farmers; 10 were cooks; 8 were mechanics; 6 were carpenters; 2 were contractors; 2 were plumbers; 2 were brick masons; 2 were policemen; 2 were physicians, and 1 each was listed as: lawyer, salesman, painter, barber, cobbler, postmaster, optician, schoolboy and "boot-legger." With such a wide diversity of occupations it was readily apparent that there could be no explanation of the occurrence of the cases as a result of any occupation or occupational condition.

Thirty-three per cent of cases were classed as in poor, 62 per cent as in moderate, and only 5 per cent in good economic circumstances.

The occurrence of cases in various areas at the same time, and the peculiar distribution of sex and age excluded the possibility of the causative agent being contained in some common vehicle such as water, milk, ice cream, or some other food.

It was apparent that the causative agent became effective in adult age groups, and to a greater extent in males than in females, and involved a higher proportion of persons in moderate or poor economic circumstances. It was reasoned that this was due to greater exposure in these groups.

Inquiry was made as to the use of alcohol containing preparations. Only 4 persons (less than 2 per cent) denied the use of such preparations. Two of these were said by other persons to be known to use alcohol. It is evident that in certain cases admission of the use of alcohol would be difficult to obtain. Seventy-two per cent of those admitting the use of alcohol also gave a history of the use of fluid extract of Jamaica ginger. It is quite possible that others used Jamaica ginger without being aware of it, as it seems to have been the practice of some liquor dispensers to add this product, believing that a more potent compound was the result.

The fluid extract of Jamaica ginger used was not confined to the product of any one distributor, nor to one particular brand. According to labels and samples collected from various sources, Jamaica ginger of a variety of brands had been used. This product seems to have been readily available at smaller grocery and drug stores, was relatively less expensive than certain other alcohol containing preparations, leading to the term applied by some, "the poor man's drink," as it could be obtained in small quantities, and with consequently less outlay of funds. It was thought by some users that this product gave a quicker reaction with less after effects. The burning sensation to mucous membranes was overcome by dilution with water or soft drinks of various kinds. Some persons, however, stated that the material was used without dilution.

The history as to the time of last using alcohol was obtained in as many instances as possible. In the case of more or less constant users, this information was not of much value. From certain other individuals, it is evident that no great reliance could be placed on the information obtained, as the date could not be fixed with any degree of accuracy. However, 53 per cent of cases stated that the time of last using alcohol before appearance of paralysis was between 1 week and 1 month previously, 32 per cent stated it was less than 1 week, and 15 per cent that it had been more than 1 month.

There appeared to be no relation between the amount of the fluid extract of ginger consumed and the severity of symptoms. Apparently small amounts in some individuals produced the same result as very much larger amounts taken by others. It seems safe to assume that the paralysis did not occur in all persons exposed to the causative

agents. Apparently reliable histories were obtained in which it was noted that of several persons, members of the same party, and exposed in essentially the same manner and degree, some subsequently developed the paralysis and others did not.

The date of onset was obtained as accurately as possible. Seventy-two per cent of cases had an onset within the first 10 days of March, 21 per cent before, and 7 per cent after this period. All but 3 had an onset within a period of 30 days.

Taking into consideration all the data at hand, it seemed reasonable to assume that the cause of this condition was closely associated with the use of alcohol, and the evidence pointed very strongly toward the probability of one alcohol containing product, namely, fluid extract of Jamaica ginger, being the vehicle involved. It should be emphasized, however, that neither alcohol of itself nor the standard fluid extract of Jamaica ginger was considered as a causative agent, but rather that the sub-standard fluid extract acted as the vehicle by which the actual causative agent was enabled to enter the human mechanism.

FURTHER PROGRESS OF CASES

The further progress of these paralytic cases has been watched with a great deal of interest, by practicing physicians, public health officials, and the lay public. Opinions differ as to the prospect of complete recovery, and the progress made toward this hoped for outcome. An opportunity for the study of the pathology of the condition was afforded by necropsy following the death of one individual from intercurrent causes. This was reported by Dr. Hugh Jeter.³ Briefly summarized, the results of the preliminary examination were the finding of a definite lesion of the peripheral nerves and no evidence of any such lesion of the cord or brain. This consisted of a perineural exudate composed largely of lymphocytes, many of which were large; a few scattered polymorphonuclear leukocytes; many red cells, and a slight amount of fibrin. This perineural exudate was stated to be most certainly an acute process limited to the peripheral nerves, and in patches along the nerves. No microorganisms could be demonstrated in the exudate, nor was there evidence of any acute chemical poisoning.

Some observers are of the opinion that definite but very slow improvement is being noted, while others believe that the seeming improvement is due to the education of other muscles to take over in part the functions of those whose nerve supply has been disturbed. Certainly the progress toward recovery is very slow. No complete recoveries have been reported, notwithstanding the fact that more than 6 months have elapsed since the development of the paralysis.

LABORATORY STUDIES

A plan of study from a laboratory standpoint was projected by the Tennessee Department of Public Health in coöperation with the Vanderbilt University School of Medicine. The results of this study will be available at a later date.

A preliminary report by Dr. Maurice I. Smith⁴ and others from the National Institute of Health (Hygienic Laboratory) of the U. S. Public Health Service indicates through pharmacological and chemical studies that the cause of this unusual type of paralysis is probably a phosphoric acid ester of tricresol. Further experimental work is being carried out along these lines at this institution.

National Association of Juvenile Courts

IN compliance with a resolution passed at the International Child Welfare Congress held in Paris in 1928 and calling for the organization of an International Association of Judges of Juvenile Courts with national organizations within each country, a royal decree issued by the King of Spain on May 16, 1930, provides for the organization of a National Association of Juvenile Courts in that country. Among the purposes of the organization the decree mentions the study of questions relating to the work of the juvenile courts, promotion of coöperation between these courts, work for the establishment of new juvenile courts, training of the staff of the juvenile courts and investigation of matters relating to the work of these courts.

Agglutination Tests for the Diagnosis of Undulant Fever*

S. BAYNE-JONES, M. D.

School of Medicine and Dentistry, University of Rochester, Rochester, N. Y.

IT seems obvious that coöperative investigations by public health laboratories in a state should add interest to the work of the laboratories, increase the solidarity of their association, and yield results of general value. A statement of the ideal, however, does not remove the difficulties which lie in the path of such an undertaking. The selection of a topic of sufficient interest to all members of the association, the choice of work which lies within the capacities of the individual laboratories to perform, and the arrangements for a central office for the supply of materials and information and for the collection and handling of the reports of results, are important details to be arranged outside of any solution of the problem under investigation.

In order to find out whether the independent laboratories of the New York State Association of Public Health Laboratories could carry through a coöperative investigation and derive the expected benefit from the effort, it was decided by the association, in 1928, to embark upon a joint enterprise in 1929. The topic chosen for investigation was "Agglutination Tests for the Diagnosis of Undulant Fever." Although this topic was not original, it was timely.

The plan was to use for these tests specimens of human serum received at the laboratories for any sort of examination. It was thought that by making agglutination tests with these serums and a suspension of *Brucella abortus*, positive results would be obtained in cases in which undulant fever had not been suspected, as has been the experience elsewhere during the past few years in which many previously unrecognized cases of undulant fever have been uncovered by means of routine agglutination tests.

It was hoped that these tests would give some information as to the incidence of undulant fever in different parts of New York State and it was expected that tests with serum from patients suffering with

* Report of a Coöperative Investigation by Members of the New York State Association of Public Health Laboratories during 1929.

a great variety of diseases would throw additional light upon the specificity of the reaction.

The coöperative investigation was conducted according to the plan from January 1 to December 31, 1929. The following is a report of the methods used and of the outcome of the work.

As this report deals primarily with an enterprise of the New York State Association of Public Health Laboratories, a general review of the literature on undulant fever in this country has not been included in it. Extensive bibliographic reference to the important and well known work which has been done on this subject in the past few years was thought to be unnecessary here, as excellent reviews of this work are generally available.

METHOD

The offer of the Rochester Health Bureau Laboratories to serve as headquarters for this investigation was accepted and during the year all correspondence and supplies of materials were handled through the office of those laboratories. After consultation with the State Laboratory, a standard procedure was adopted for the agglutination tests. Letters were addressed to 57 approved laboratories throughout the state inviting them to take part in this investigation. Of these, 21 indicated a willingness to join in the enterprise. The number, however, was reduced by various circumstances to 17. Table I gives a list of the laboratories in which the work was carried out during the year. In these, 3,716 specimens of serum were tested for agglutinins for *Brucella abortus*. The location of the laboratories and the location of cases with positive agglutination reactions are shown on the accompanying map (Figure I). As will be seen from an inspection of the table and map, the coöperating laboratories were well scattered throughout New York State.

PROCEDURE

The antigen was supplied in 100 c.c. bottles. Agglutinating serum for repeated controls of the sensitivity of the antigen was supplied in 1 c.c. vials. These materials were sent out with the following description and rules for performing the tests:

Antigen—The antigen is a saline suspension of a culture of *Brucella abortus*, Strain No. C209, obtained from the New York State Laboratory at Albany. This strain was originally isolated from cow's milk. The organism was grown on glucose meat infusion agar pH 7.4, washed off with saline solution and killed by heat at 60° C. for 1 hour. The suspension was diluted with 0.85 per cent NaCl solution containing 0.1 per cent formalin to match in density a No. 3 barium sulphate stand-

ard. Before using the antigen, shake up the suspension thoroughly. Control agglutination tests with this antigen have been satisfactory.

Anti-abortion Serum—This vial contains 1 c.c. of diagnostic agglutinating serum for undulant fever. This serum is to be used as a control for the agglutinability of the antigen suspension of *Brucella abortus* in each day's series of tests.

This serum is now diluted with an equal amount of 50 per cent glycerin. For the control test use a final dilution of 1-400.

Add 1 c.c. of this glycerinated serum to 99 c.c. of salt solution containing 0.5 per cent of phenol. This gives a dilution of 1-200. Use 0.3 c.c. of this dilution in the control test.

This diluted serum should keep satisfactorily in the icebox for 6 months or longer.

Procedure—1. Use 0.3 c.c. amounts of serum diluted 1:5, 1:10, 1:20, 1:40, 1:80, 1:160. The final dilutions when equal amounts of culture suspension are added will be double these (e.g. 1:10 through 1:320). In case agglutination is obtained in the 1:320 dilution, test higher dilutions of the serum in order to determine the titer.

2. Use two control tubes, one containing 0.3 c.c. of saline plus 0.3 c.c. of antigen to make sure that the suspension remains homogeneous, and one containing 0.3 c.c. of a known agglutinating serum plus 0.3 c.c. of antigen. Check up the agglutinability of the suspension.

3. Use 0.3 c.c. of the antigen culture suspension in each tube.

4. Use tubes measuring 11 by 75 mm.

5. Fresh or inactivated serum may be used.

6. *Incubation*—Incubate the mixtures for 2 hours at 37° C. Record the reactions. Place the tubes in the icebox over night and record the results.

7. *Recording of reactions*—Read the tests in the morning and record the degree of agglutination as follows: 4 + = complete agglutination, supernatant fluid clear, all large clumps; 3 + = supernatant fluid clear or nearly clear, very definite clumping; 2 + = supernatant fluid not clear, definite clumping; + = supernatant fluid not clear, very small clumps definitely visible to the unaided eye; — = suspension uniformly turbid, no clumping.

All laboratories are requested to follow this procedure, which is based upon the *Standard Methods of the Division of Laboratories and Research of the New York State Department of Health*. If a different procedure is being followed in your laboratory, please do the test by both methods when possible and record the results of both tests for comparison.

Records—Printed cards with headings and spaces for notations are being sent to you. Please give all the information asked for on this card and add any additional appropriate information. It is requested that all records for the association be kept on these cards to secure uniformity and facilitate compilation. Cards may be returned periodically or at the end of the year.

Various comments were received on the antigen. Dr. Charles Carpenter found this suspension less agglutinable than the living cultures which he has used in his work. Undoubtedly it was not a highly sensitive antigen. Its sensitivity, however, was apparently sufficient to give good results in cases of undulant fever and probably reduced

the number of weak reactions without loss of diagnostic precision. Its keeping qualities were excellent, as it lost none of its sensitivity during a year. In the tests it served as well as a suspension of *Brucella melitensis* from true malta fever in man, which was used by the State Laboratory in a number of agglutination tests made in parallel with those using the suspension of *Brucella abortus* C209. The usual type of agglutination clumps obtained with this antigen was finely granular. The clumps formed slowly during the 2-hour period of incubation at 37° C., and were not readily visible until the tests had been allowed to stand for 18 hours in the icebox at about 4° C.

The immune serum used as a positive control was obtained in several ways: 1. Abortus serum prepared at the State Laboratory at Albany by immunizing rabbits against *Brucella abortus*. 2. The mixture of the serums of rabbits immunized against *Brucella abortus* and *B. melitensis* prepared in this laboratory. 3. Serum from patients with undulant fever containing agglutinins for *Brucella abortus*. All of these serums had titers greater than 1-2,000 for the strain of *Brucella abortus*, C209, used in these tests. The rabbits were immunized by subcutaneous and intravenous injections of suspensions of killed *Brucella abortus*.

To provide for all use made of the reagents, 5,500 c.c. of antigen suspension were supplied and 33 vials of agglutinating serum were sent out.

RESULTS

Agglutination produced by a 1-100 dilution of the patient's serum was considered diagnostic or positive for undulant fever in this investigation. Of the 3,716 specimens reported upon, 64 gave agglutination in a titer of 1-100 or higher. The percentage of positive reactions in this series was, therefore, 1.72 per cent. Agglutination in some dilution of the serum, from 1-10 up to 1-10,000, was given by 165 or 4.44 per cent of the 3,716 specimens. With the exception of serums from two "old cases" of undulant fever, whose titers were 1-80, no specimen giving agglutination in a dilution less than 1-100 seemed to come from a case of undulant fever. These results are summarized in Table I.

In 10 cases of typhoid fever, the serum gave agglutination with the abortus antigen in 1-10 to 1-40 dilutions. On the other hand, 180 specimens from patients suspected of having typhoid fever were entirely negative. It is probable that an undetermined number of these patients actually had typhoid fever. These results bearing on the specificity of the agglutination reaction for the diagnosis of undulant

fever have significance in connection with the large amount of negative evidence included in the reports received during this investigation. The report cards listed 95 different clinical diagnoses, including most of the infectious diseases and many obscure febrile conditions. Among these reports of specimens giving negative undulant fever agglutination

False reactions were occasionally obtained with serum containing hemoglobin. The experience of Dr. C. A. Bentz, in Buffalo, and of those at the State Laboratory at Albany, indicates definitely that "hemolized serums" may give false reactions in dilutions as high as 1-320. Two such cases were carefully investigated by Dr. Bentz. These specimens were from patients with typhoid fever. In these cases the agglutinin titer was 1-320 with specimens of serum showing the results of hemolysis. Two days later, specimens free from hemoglobin, from both of these patients, gave absolutely no agglutination. From this experience, it is evident that positive agglutination in hemolized serum should not be accepted as diagnostic until confirmed with serum free from hemoglobin.

Of the 64 “positive cases,” one originated in Pennsylvania. The remaining 63 were distributed throughout the following 28 counties of

New York State: Albany, 4; Broome, 4; Cattaraugus, 1; Chautauqua, 2; Chenango, 3; Clinton, 1; Columbia, 1; Erie, 5; Essex, 1; Franklin, 1; Genesee, 1; Greene, 2; Herkimer, 4; Jefferson, 1; Lewis, 1; Monroe, 7; Oneida, 3; Ontario, 1; Orleans, 1; Putnam, 1; Rensselaer, 1; Saint Lawrence, 1; Schoharie, 2; Steuben, 6; Warren, 4; Washington, 2; Wayne, 1; Westchester, 1. While there are undoubtedly focuses of undulant fever in New York State, this survey is inadequate to indicate their location. It suggests, however, that there may be an unusual prevalence of the disease in the counties of Monroe, Albany, Broome, Warren, Erie, Steuben, and Herkimer. In most of these counties, the presence of a large laboratory engaged in active investigation may be responsible for the greater number of tests and therefore a greater number of positive findings. In view of this and other possibilities, it would be unwarranted to use these statistics for more than they purport—namely, a location of patients whose serums give positive agglutination tests for undulant fever.

The age group distribution of patients in this series from whom serum was obtained giving positive agglutination reactions with *Brucella abortus* is much the same as that found in other similar investigations. Most of the positive reactors, 53 per cent, were in the age group 15 to 39 years. No children in the first year of life and only 1.6 per cent of children under 10 years of age gave positive reactions. As the specimens were drawn largely from adults, it is not justifiable to accept this difference as indicating the actual difference in incidence of the disease in persons in these age groups. Nevertheless, the conformity of these figures with those of others who have studied this problem is noteworthy. Undulant fever in this country is undoubtedly most common in adolescents and young adults.

More males than females gave positive reactions. The percentage of males (65.8 per cent) was twice that of the females (32.8 per cent). While no statistical studies have been made to determine the correlation of positive reactors according to sex with the proportions of the sexes in the whole series, it can be stated that there was no great excess of males among those from whom the specimens were taken. This higher incidence of positive reactions among males has been brought out repeatedly in studies of the incidence of undulant fever.

Among the occupations of the patients whose serums gave positive agglutination tests, farming was the one which was most often associated with undulant fever. Farmers and their wives made up 23.2 per cent of those who gave positive reactions. The incidence among those on farms is in fact somewhat higher than this, as a number of others who followed a principal occupation other than farming lived on farms.

Not reported	1	1.6			
Total	64	100.0			

In a few of the cases, an investigation was made of the milk supply of the patients giving positive agglutination reactions. Since this was not done in all cases, it is impossible to make a definite statement on the relationship of the use of raw or pasteurized milk, and the handling of cows to the incidence of undulant fever among the 64 cases listed in this series. The drinking of raw milk, the use of raw milk from cows in herds in which infectious abortion occurred, the milking of cows, and assistance in the delivery of calves, were frequently noted in reports on patients whose milk supply and habits were investigated. In a few cases, no evidence of the use of raw milk or contact with cattle could be obtained. Contact with swine was infrequent. Blood cultures were made in only 9 of the 64 cases. From 2 of these, organisms of the *abortus-melitensis* group were isolated. Whether these organisms are of the caprine, bovine or porcine type has not yet been determined.

Since the conclusion of this investigation, the question has arisen as to what may be expected from routine agglutination tests for undulant fever with all specimens of serum received at a laboratory. It is difficult to determine from examination of the records exactly how many positive reactions were obtained with specimens from patients whose illnesses did not arouse some suspicion that they might be due to the bacterium of undulant fever. Certainly, such cases were in one sense very few, and will undoubtedly become fewer now that attention is increasingly directed to the possibility that prolonged, irregular fevers,

arthritis, debilitated states, and intestinal and abdominal disorders may be manifestations of undulant fever. In such cases, it should become a routine procedure to examine the serum for agglutinins for organisms of the *Brucella* group. A few positive reactions will be obtained with serums in the general run of specimens submitted for serological tests for the diagnosis of syphilis. But the results of this investigation indicate that the physician and the laboratory can obtain information of the greatest value by having agglutination tests done in all cases of obscure fevers, and also in many periodically febrile cases in which the clinical diagnosis was that of probable tuberculosis, probable typhoid fever, probable "rheumatism" and probable malaria.

SUMMARY AND CONCLUSIONS

During the year 1929, 17 laboratories in the New York State Association of Public Health Laboratories undertook a coöperative investigation of undulant fever. The work was limited to the performance of the agglutination test with serums submitted to the laboratories for any purpose. An antigen composed of a suspension of killed *Brucella abortus* was used and a standard procedure was followed by all of the laboratories engaged in this work. Supplies were sent out from and reports were returned to a central laboratory. The investigation proceeded according to plan without difficulty, demonstrating that laboratories of this type, under directors appreciative of the value of investigation, could coöperate in a joint enterprise and obtain from the work information of both local and general value. While not an epidemiological study of undulant fever, this investigation furnishes some additional and confirmatory information on the incidence and distribution of the disease in New York State.

Reports were made on agglutination tests with serums from 3,716 patients. Of these, 64, or 1.72 per cent, gave positive agglutination reactions with the *Brucella abortus* antigen. All except one patient lived in New York State. While the final diagnosis in some cases had not been made, this investigation seemed to indicate that all of these were cases of undulant fever.

Agglutination reactions with dilutions less than 1-100 were obtained with 93 specimens of serum. With the possible exception of 2 old recovered cases of undulant fever, the diagnosis of undulant fever was not made in these cases.

Some degree of agglutination with the abortus antigen or melitensis antigen was obtained with 165 serums (4.44 per cent).

False positive reactions were given with serums containing hemo-

globin. No other known false positives occurred among many specimens from patients suffering from a great variety of diseases.

Among the patients whose serums gave positive reactions, those between the ages of 15 and 39 were most numerous (53 per cent). Males occurred in the series twice as often as females. Farming and occupations associated with farming and cattle raising were the occupations most frequently associated with positive agglutination reactions for undulant fever in this series. While the drinking of raw milk and contact with cows in herds having infectious abortion could be established in nearly every case in which a positive agglutination reaction was found, there were some instances in which these factors could not be shown to exist. The reports do not furnish information on the milk drinking habits and association with cattle of the 3,547 patients whose serums gave no agglutination with the abortus antigen. Contact with swine was infrequent and unimportant according to the reports on the cases in this series.

The discovery of cases of undulant fever was made through the use of the agglutination test. The experience of this investigation, however, indicates that very few positive reactions will be found from tests with the serums submitted for serological tests for syphilis in the ordinary course of medical practice. On the other hand, valuable and often decisive information will be obtained from routine agglutination tests with serums from patients suffering from obscure and periodical fevers, arthritis, intestinal and abdominal disorders, and with suspected tuberculosis and typhoid fever. It seems advisable to have this test performed as a routine procedure in many of these febrile conditions even when the clinical diagnosis has an aspect of assurance.

The Ganges and Public Health

THE year 1930 was marked by one of the largest religious festivals in India, which is held every 12 years, and which brought to Allahabad three and one-half million pilgrims, two and one-half million of whom bathed on the same day, January 29, in the Ganges. Great preparations had been made to assure the distribution of pure water, to ferret out the sick and place them in hospitals, and to increase the vaccinations. Only 168 cases of cholera were treated, and cholera was less frequent in India during the following two months than during the corresponding period of the preceding years.—*Pub. Health Rep.*, Nov. 7, 1930.

The Industrial Nurse in Gear with the Machinery for Human Adjustment*

VIOLET H. HODGSON, R. N.

*Assistant Director, National Organization for Public Health Nursing,
New York, N. Y.*

THE basic objective of all public health nursing is the satisfactory adaptation of the individual to an environment that makes health possible. The adaptation may be physical, mental, spiritual, social or economic. Whichever it may be, each must be considered in relation to all the others if we wish to obtain an harmonious adjustment of the integral parts of the human machine. The environment may be the home, the school, or the plant. Each offers peculiar situations to which the human machine must be adjusted if production of all things necessary to health and happiness is to reach its maximum.

If industrial nursing shares this basic objective with other activities in the field of human adjustment, it immediately becomes evident that the service is not that of a simple one-unit machine, but a part of that more complex mechanism designed to produce the most satisfactory adjustment of the individual to his environment, which is naught else but the attainment of individual maximum capacity for production in the plant, the home and the community. It simply means that the industrial nurse must be in gear with this machinery for human adjustment. Coördination and proper sequence of all the gears in the community health machinery are essential in order to attain the maximum speed in making productive human adjustments with a minimum of friction and lost effort. The industrial nurse has a very real contribution to make to this process within and without the plant, if she is "timed" to perform her part in "proper sequence" with all the other agencies.

WITHIN THE PLANT

The intra-plant relationships are admirably expressed by Bruere and Pugh in their definition of industrial relations: "The modern art of industrial relations is the act of courteous, coöperative accommodation of interests between employers and employees with a view to the successful operation of the business in which they are concerned."

* Read before the Virginia State Nurses Association, Virginia Beach, Va., May 23, 1930.

The health service of the nurse can be a real factor in increasing the effectiveness of such a program, if a coöperative relationship is maintained with the groups responsible for the administration of its various services.

The average worker is interested essentially in his earnings upon which he depends for the material things necessary for his health and comfort. About one-third of his time is spent in business. Modern management, although primarily interested in the quality and quantity of production of goods, has long since recognized that the healthy and happy worker is the greatest asset in attaining these objectives. The nurse in industry has the interests of both groups in mind and consequently makes her greatest contribution through the integration of her services toward the ultimate goal of satisfactory human relations within the plant.

The Physician—Through the practice of her nursing skills in the care of the sick and injured, under the direction of a physician, she helps the worker in reducing time that might otherwise be lost from minor accidents and injuries. This is a service of interest to employer and employee. Of more importance, though less accurately measurable, is her opportunity for prevention of incapacitating physical conditions, through education of workers in matters pertaining to health, and guidance in securing necessary medical service, both diagnostic and remedial.

The Safety Engineer—If the nurse is acquainted with, and interested in, the objectives of the safety engineer, she can assist him in interpreting his program of accident prevention to the worker and secure to the latter the means whereby he can coöperate most effectively in developing and promoting safety measures. No better opportunity is provided for doing concrete teaching than at the time when the employee is suffering from an infraction of the safety rules. Wise instruction at this time will enlist the active interest of the worker as a disciple of the gospel of prevention which he can share with his fellow workers. In like manner, keen observation and analysis of conditions which come to her attention in the first aid room will disclose many situations which should be called to the attention of the safety engineer for correction.

The Personnel Manager—The personnel manager recognizes the importance of mental health as well as physical in the satisfactory adjustment of the worker to his job. Production depends on adjustment to the work, fellow workers, and the foreman. Lack of understanding will result in excessive friction in the human machine with its concomitant loss of energy and, in extreme cases, in the eventual

breakdown of the machine itself. Recent studies in industrial fatigue have revealed the amazing influence of psychological factors in fatigue and variations in production. Rest periods have been found to relieve the monotony of repetitive processes, but release from disturbing mental factors has transcended the effects of physical rest. The opportunity to talk about anything that is troubling him has been, in many cases, all that was necessary to restore the worker to his original capacity for production. In the study, carefully selected individuals were chosen to provide this service to the employees. Although, at the present stage of the experiment, this would seem to be the ultimate function of the foreman, the part which the nurse can play in such a program has not been lost sight of. Through a sincere interest in the employee she should be able to gain his confidence so that he will seek her counsel in matters of mental and social as well as physical adjustment.

Public health nursing in industry is indeed but one of the many gears in the plant machinery for adjusting the employee satisfactorily to his environment.

IN GEAR OUTSIDE THE PLANT

Thus far it would seem as though our conception of the health needs of the employee depended entirely on the plant environment and his relation to it. Such is far from being the case. As a social being, the job is but the means whereby he can develop those instinctive social relationships upon which the whole structure of society depends. Participation in family and community life is essential in the well balanced life of the worker. Maladjustments of the parts of this machinery are reflected in the "loss of power of the driving wheels" in the plant.

Illness in the home may result in physical and emotional fatigue which inhibits the employee's output in the plant. In order to serve the interests of employer and employee most effectively, it becomes the responsibility of the nurse to take into consideration the needs of the employee in the home in so far as their influence affects his welfare in the plant. To do this requires a knowledge of the facilities available in the community for hospitalization, care of the sick in the home, and supervision of the health needs of each age group.

Furthermore, so closely can her teaching in the fundamental principles of personal and plant hygiene coincide with those of the visiting nurse and school nurse that we can truly speak of the joint efforts of all public health nurses in terms of a family and community health program. This objective can only be attained through close relation and adjustment of the parts in the community health machinery.

Personality difficulties are not confined to contacts outside the home. Management is aware of the unproductive friction caused by maladjustment of the employee to his fellow workers and to the foreman. Similar, and perhaps more devastating, waste results from social maladjustments outside the plant. Accidents are not always the result of ignorance and deliberate breaking of the safety rules. Mental preoccupation with an unhappy marital relationship may divert the mind of the employee just long enough to cause him to forget to replace the guard on the machine which later produces the injury. It is the wise nurse, with sound judgment and a real human interest, who will be able to sense situations which contribute to the problems of accident and illness observed in the plant, and who can act as a counselor without arousing the antagonism of the worker.

Modern management is averse to interference in the affairs of the worker outside the plant—and rightly so. On the other hand, helping the worker to help himself is but a fundamental principle upon which constructive health and social work is based, and in no wise partakes of the nature of paternalism. It is here that the art of human relations must be exercised with the greatest skill, if the nurse wishes to be of greatest service. Wise guidance to the community facilities available for administration of the service most needed at the time is all that devolves upon the nurse. Knowledge of and coöperation with the community machinery are prerequisites for the proper relationship of the gears in the machinery for such human adjustment.

The employee who comes to the nurse with problems of delinquency, lack of parental control, need of hospitalization, and other situations in the home, should expect guidance which conforms with the best accepted practices within that community. The advice of the industrial nurse should not run counter to that of other health agencies but should reinforce in the mind of the worker the instruction which his family may have received from the administering agency. Not infrequently it becomes her privilege to "close the sale" of a family health program. The preventive program of the local health department may offer exceptional opportunities for the plant nurse to assist in the prevention and control of communicable diseases.

Even of greater importance do these relationships become when we realize that health service in industry is largely confined to plants with 250 or more employees on the pay roll, and that a vast field remains uncovered in the smaller establishments, whose combined employment is slightly less than 50 per cent of the total. Here would seem to be a splendid opportunity for the local public health nursing association to extend its health services to all the members of the family, and in so doing might appropriately consider the necessary adjustments of their

program and the other community health machinery to meet the needs of industry.

The nurse in industry is one of a large group of health workers who has especial opportunity to emphasize the preventive rather than the curative aspects of disease. If the nurse is to keep pace with the progress that is being made in public health nursing, and if she expects her industrial nursing program to meet the needs of modern preventive medicine, it is of the utmost importance that she not only belong to her state and national nursing organizations, but that she contribute to their programs and share her experiences with her coworkers.

The nurse in industry profits by the stimulation that comes from discussing her problems with other workers in the public health field. The viewpoint of others is invaluable in broadening her own, and the entire group needs her contribution in developing and improving standards in the public health field.

CONCLUSION

Thus far our topic has been treated from the positive point of view, assuming the industrial nurse was in gear with the machinery for human adjustment in the plant and in the community. Unfortunately, there is a negative aspect, analogous to the situations found in maladjustment of the gears in a machine. "Too much play between the teeth of the meshing gears," "stripping of the gears," "lack of care in operation," and "unrelated gears," each, in turn, produces a condition in which "coördination and proper sequence" are interfered with, resulting in lost energy and interruption of power transmission from the motor to the drive wheels. Loss of time in reporting problems to other agencies, unwillingness to coöperate, resulting in a clashing of interests, neglect of the routine procedures of reporting, which are the mechanics of coöperation, and uncoördinated objectives are the counterpart situations in the machinery for human adjustment which result in a lessening of production and efficiency in helping the individual make a satisfactory adaptation to his environment.

As the efficiency of the plant machinery depends upon the skillful supervision of the mechanic, so, too, does the effectiveness of our social machinery depend upon the art of administering to the needs of the human machine. To the nurse in industry is afforded unequalled opportunities for the development of this service, not alone through her professional ministrations, but likewise in the practice of that more fundamental service, the art of human relations.

THE FORT WORTH MEETING

FOR its fifty-ninth Annual Meeting, our Association chose the great Southwest, selecting the thriving city of Fort Worth, the site of an old fort.

All the forebodings that the distance from the North and East would have an injurious effect on the attendance were shown to be unfounded. The registration was 1,139, which compares favorably with other meetings, except those in one or two of the large eastern cities.

Particular interest attached to this meeting on account of the fact that it was the first held since our reorganization in 1929, and the first for which the newly created Committee on Meetings and Publications had arranged. All of the different sections had excellent programs, many in the form of symposiums, some of which were unusually notable and of extreme value to public health workers.

The meeting was especially important, as it marked what might be called the re-entrance of our sister Republics to the south into our deliberations. As Dr. Silva, Chief of the Department of Public Health of Mexico, pointed out in his address, our country has gone through the greatest of world wars, and his country has gone through much suffering during recent years. It was altogether an auspicious occasion, and we may well rejoice at once again taking up the lines which are of necessity of common interest to us, and reviving the delightful friendships which did so much to make our Association truly international in character in the past.

For the first time in the history of the Association, important representatives of the Health Services of all of our constituent members, Canada, the United States, Mexico, and Cuba, were present. Mexico was represented by 23 delegates, headed by the Chief of the Department of Public Health and a number of his staff.

Canada had 18 delegates, with Dr. Amyot, Deputy Commissioner of Health of the Dominion at its head.

Cuba was represented by Dr. Aristides Agramonte, who was elected to Honorary Fellowship in the Association on account of his notable career, and who gave an excellent address at the final banquet.

The State of Texas and the City of Fort Worth excelled themselves in hospitality. Their greeting was most warm, and continued throughout the stay of the delegates. Certainly the far-famed hospitality of the South was exhibited at its best.

Over 200 went on the post-convention tour to the City of Mexico, and there was universal regret among the delegates that all of them could not take part in this, which will doubtless further cement the bonds of friendship.

AIR CONDITIONING FOR PREMATURE INFANTS

IT has long been recognized that one of the first prerequisites to start the premature infant on his way to independent existence is the conservation of body heat and energy. The necessity for maintaining a constant temperature accounts for the popularity of the small incubator, but very recent studies by Blackfan and Yaglou* show that moisture and an ample supply of pure air are equally important, and that they are more readily and adequately controlled in a room by means of general air conditioning than in a small incubator.

After a 4-year study of the influence of air conditions on the growth and development of premature and other delicate infants, these workers arrived at certain requirements from a consideration of 4 valid criterions: stability in body temperature, gain in weight, incidence of diarrhea and of mortality, and general behavior of the infants under various air conditions. The air conditions were obtained by means of a modern conditioning system capable of warming and humidifying the air in winter and cooling and dehumidifying it in summer to any desired degree, regardless of outdoor weather.

The application of such a system to the premature nurseries of the Infant's Hospital in Boston resulted in marked improvements in the care of these infants. Stabilization in body temperature was associ-

* The engineering aspects of this work have already been published in the *Heating, Piping, and Air Conditioning Journal* for 1930.

ated with reduction in the incidence of diarrhea and in the general mortality. Infections were reduced to a minimum and gains in body weight increased.

In order to keep the atmosphere free from odors and maintain the desired temperature and humidity, a ventilation rate of 25 air changes per hour was required, and this had to be effected with an air movement not exceeding 15 feet a minute in order to avoid drafts.

Although we do not know the physiologic significance of the relation of odors of human origin to general ventilation work, evidence seems to warrant the conclusion that there are substances in the air of unventilated occupied spaces—even when the temperature and humidity are controlled—which in some way are capable of producing headache, nausea, loss of appetite and a disinclination for physical activity. These are sufficient to warrant adequate ventilation, particularly in the case of premature infants who are much more susceptible to infection than adults.

In addition to the physical heat loss, the moisture content of the air was found to exert a profound physiologic effect upon these infants. When a relative humidity of 30 per cent—a considerably higher value than that prevailing in unconditioned nurseries during cold weather—was maintained for 2 weeks or longer, the body temperature became unstable, gains in weight diminished, the incidence of diarrhea increased and the mortality rose. On the other hand, continuous exposure to air conditions with 55 to 65 per cent relative humidity gave very satisfactory results over a 2-year period. The best relative humidity was found to be 65 per cent.

The requirements for temperature depended to a considerable extent upon humidity. When the humidity was fixed, the temperature varied according to the general constitution of the infants and their body weight. For normal prematures the variation was from a minimum of 75° F. for infants weighing 4½ to 5 pounds to a maximum of 88° F. for infants weighing between 1½ and 2 pounds. For congenitally diseased infants, the variation was from 76° F. to 100° F. This latter group was cared for in individual electric incubators placed inside the conditioned nurseries, and the heat adjusted according to requirements. In this way, the infants benefited from breathing the comparatively cool room air at about 65 per cent relative humidity.

The striking benefits are attributed not only to improved air conditions but also to advances in medical treatment and to improvements in nursing and general care. It is fair to conclude, however, that the introduction of mechanical air conditioning has proved a distinct advance in the care and treatment of premature infants.

THE TEETH AND DIET

IT is hard to escape the conclusion that oral hygiene is one of the neglected fields of preventive medicine. It is true that we have had toothbrush drills for some years and here and there an outstanding dental surgeon has raised his voice like "one crying in the wilderness." While the general facts as far as known have been more or less widely accepted, progress has been slow.

Miller, an American who did most of his work in Berlin, was one of the first to teach dental hygiene on what he considered a scientific basis. Following his views it has been generally held that caries depends upon conditions external to the teeth and it is hardly too much to say that even now the most prevalent idea is that carbohydrate stagnation is the chief cause of decay in teeth. The prevention of apical abscesses has not been successful while doctors and dentists, alike, have gone through an orgy of tooth pulling for the cure of practically all ailments for which some other definite cause could not be determined. Many types of toothbrushes and dentifrices fill our drug stores and advertisements pack the pages of current literature; yet it seems probable that conditions have not grown much, if any, better, unless the advice so widely given, to consult a dentist at least annually, has brought them about.

In England, where the dental conditions of children seem to be less favorable than in this country, the matter has engaged the attention of the Medical Research Council, largely on account of observations made by E. Mellanby in his epochal studies of rickets, during which he proved the power of the antirachitic vitamin, now known as D, and showed its controlling influence over calcification. Along with this he showed the injurious effect on calcification of certain cereals, especially oatmeal.

The extensive work of May Mellanby¹ has confirmed his findings and greatly advanced our knowledge along these lines. The proof has been given largely by experiments on dogs, but human studies are in progress, which so far have strengthened the conclusions drawn from animal work.

The teeth are a good index of calcification at varying periods during development, and not only their general development but their microscopic structure can be influenced and even determined by diet. Generally, foods containing a large amount of vitamin A are necessary; but D, which has now been shown to be a separate entity, is the determining factor and is found in varying amounts in foods contain-

as egg yolk, milk, and cod liver oil, or by irradiation of foods in which the ergosterol content is changed.

The production of perfect teeth also depends upon the presence of calcium and phosphorus in the diet. If the diet contains an abundance of vitamin D the required amount of these salts may be very small, but if the vitamin D intake is low extra calcium improves the teeth. In the absence of vitamin D perfect calcification does not take place no matter how much calcium and phosphorus is contained in the diet.

Sunlight may bring about the formation of good teeth even on diets which are defective, and irradiation has a similar effect, though improvement is not nearly so great as that produced by an abundant supply of vitamin D.

Certain cereals, especially oatmeal, seem to contain a material called by E. Mellanby "toxamin," which interferes actively with the normal development of teeth, but its evil effect is manifest only when there is an insufficiency of vitamin D, and is counteracted by an abundance of this substance. Exposure to sunlight, the good effect of which is recognized, has in some cases been ineffective when the diet contained a large amount of anti-calcifying substance. The amounts of calcium and phosphorus necessary for perfect calcification vary with the vitamin D content on the one hand and the toxamin content on the other. No explanation of this fact has yet been brought forward.

There are two practical applications of the facts brought out by this research. First, in point of time, is a proper diet for the mother during pregnancy and lactation, though it has also been shown that stored vitamins either in the mother or in the offspring may be utilized during a period of deficiency. The food which the mother receives affects not only the temporary but also the permanent teeth. The feeding of the offspring with an abundance of vitamin D is especially important for the permanent teeth, as the deciduous teeth seem to benefit by the vitamin stored in the mother's tissues before and during pregnancy and lactation.

It seems clear that by proper feeding of parents and young children defects in the structure of the teeth which are largely responsible for caries and other dental diseases may be avoided. The vast amount of dental disease which, in the aggregate, is one of the greatest sources of ill health can be appreciably prevented.

ASSOCIATION NEWS

SIXTIETH ANNUAL MEETING

MONTREAL, CANADA

SEPTEMBER 14-17, 1931

DR. AGRAMONTE AN HONORARY FELLOW

ARISTIDES AGRAMONTE, M.D.

ARISTIDES Agramonte, M.D., was made an Honorary Fellow by the Governing Council at its meeting on October 28, in recognition of his inestimable services in the determination of the method of the transmission of yellow fever and its control.

Aristides Agramonte was born on the field of battle at Camagüey, Cuba, June 3, 1869, his father being one of those patriots who lost their lives in Cuba's attempt to gain independence.

His early life was spent largely in New York. He received his Bachelor of Arts degree at New York University in 1886, and was graduated in Medicine from the College of Physicians and Surgeons in 1892. He served as Sanitary Inspector and Assistant Bacteriologist to the New York City Department of Health, and was appointed Acting Assistant Surgeon of the U. S. Army in 1898, being a member of the famous Board headed by Walter Reed which gave the final proofs of the relation of the mosquito to the transmission of yellow fever. Since 1900 he has been Professor of Bacteriology and Experimental Pathology at the University of Havana, besides holding many other positions, such as Secretary and Chairman of the Board of Infectious Diseases, member of the National Board of Health, Public Health and Charities, etc. In 1919, he was given the Breant Prize by the Paris Academy. He has served as delegate to many congresses in this and other countries.

While he is best known for his work in yellow fever, he has written also on plague, dengue, trachoma, malaria, tuberculosis, typhoid fever, the intermarriage of lepers, and other subjects.

In making him an Honorary Fellow, the Association has honored itself as well.

POST-CONVENTION TOUR OF THE A. P. H. A. TO MEXICO CITY,
OCTOBER 30-NOVEMBER 8, 1930

EMERY R. HAYHURST, M. D., PH. D., F. A. P. H. A., AND WILLIMINA M. RAYNE

*Ohio State University, Columbus, O.; and American Public Health Association,
New York, N. Y.*

THE American Public Health Association's Special of 14 cars, bearing 204 members including their families, left Fort Worth at midnight, Thursday, October 30, at the close of the Fifty-ninth Annual Meeting, for a 9-day, all-expense tour to Mexico City. This was on the invitation of Dr. Rafael Silva, Chief, Departamento de Salubridad Publica, and of President Rubio of the Mexican Republic.

At 9 A.M., Friday, October 31, the group arrived at San Antonio, Tex. A reception committee of San Antonio citizens was present with a large number of automobiles for a sight-seeing tour on the invitation of Dr. W. F. King, Health Officer. The automobiles for the trip were provided by the Bexar County Medical Auxiliary and the 3-hour itinerary included the ancient Spanish Palace, San Fernando Cathedral, the Alamo and its Court, once the "massacre fort," the famous Missions of the Conception and San José, the business center of the city with its modern skyscrapers, the famous Sunken Gardens and Japanese Tea Garden in Brackenridge Park, and a whirl through the residential and market sections.

An excellent luncheon was served in the patio of the old Hotel Menger through the courtesy of the Chamber of Commerce and the County Medical Society. The party was entertained with an orchestra and cowboy songs. Dr. W. F. King presided. The speakers were Mrs. J. E. King, President of the Bexar County Public Health Association, Walter Walthall, President of the Chamber of Commerce, Mrs. Alex

Adams, Major Mickie of the U. S. Army, William McIntosh, Editor of *The Light*, and Señor Enrique Santebanez, the Mexican Consul. On behalf of the delegation, Surgeon General Hugh S. Cumming, Dr. C. C. Young, Dr. A. H. Flickwir, and Dr. J. C. Anderson responded to the addresses of welcome. The Executive Secretary of the Association, who had accompanied the group thus far, left it to return to Fort Worth.

In the afternoon, a number of the members of the delegation accepted invitations to speak in the public schools in San Antonio, while trips were arranged to the sewage works, the water works, and other points of interest as befitted the desires of different groups.

At 4 P.M. the Special left San Antonio with a staff of 36 Mexican porters, waiters, cooks, bath-car attendants, a maid, etc. The bridge at Eagle Pass was negotiated at 9 P.M. with a welcome and no interference by the customs officials at Piedras Negras.

The delegation arrived in Monterrey next day at 12:30 P.M., and was met at the station by a military band. Dr. Silva, Dr. Miranda, Dr. Baez and other representatives of Mexico who had attended the Fort Worth sessions joined the party here, where Dr. Silva's special car was attached to the A. P. H. A. Special. The weather was murky in Monterrey and the delegates were thankful for the automobiles, driven by Mexicans and native Indians, and provided by the Medical Association of Mexico, from the depot to the Brewery Cuauhtemoc, where luncheon was provided. A city

orchestra and later a large military band filled the hall with resounding Mexican music. Dr. Guajardo welcomed the group, and Dr. B. J. Lloyd responded. From the luncheon building the delegation was taken to the beautiful new, white marble Federal Building, in which the offices and laboratories of the Health Department are located. Thence a trip was made to the hill site of Obispado or the Bishop's Palace from which a fine view of Monterrey is obtained with its circle of towering mountains. The itinerary was next through the residence section with its barred windows and doors and flat or mansard roofs, the American section, and back to the station whence the long train headed west to Saltillo, reached about 6 P.M. After a stop of 30 minutes, the train turned south with more mountain climbing through rugged areas of cactus, Joshua trees, etc., to the plateau of central Mexico. All night it seemed to be up and up.

All day Sunday, November 2, the train wound around mountain slopes, through defiles and over deep gullies, most of the time with two locomotives and with a most weird scenery of all varieties and sizes of cactus and "sticker" trees or mesquites, also sage and greasewood, but with never a pine or elm or other apparently deciduous plant in sight. What looked like apple trees were thorny huizaches. The great maguey cactus yields "pulque" and "tehuila," two native drinks of great renown. Occasional stops were made at interesting little adobe hamlets and villages with sometimes medieval haciendas and tiny chapels where the passengers intermingled with natives, most of whom had delicacies, cigarettes, chili or native wares to sell, and who posed their donkeys for photographs, although photographing certain domestic scenes was "taboo." Close inspection showed that what looked like willows were pepper trees or something else, and everything

that grew seemed possessed of stickers. Gorgeous cosmos, daisies, morning glories and flowering bushes, trees and cactuses were on every side. Occasionally butterflies swarmed, but bird life seemed scarce. The train passed areas of desert land, lava deposits, and mazes of arroyos, always flanked with mountains on either side until near Mexico City where the plateau broadened out, lakes and streams appeared and great corn, wheat and alfalfa fields, sometimes irrigated, extended to the distant mountains with herds of horses, cattle, sheep, and goats.

The famous city of Queretaro with its ancient viaduct was reached about 2 P.M., Sunday, and Mexico City itself at 9:30. The original plan called for arrival at 1:30 P.M., and a folklore pageant "Hamarandecua" had been arranged for 4 P.M. at the outdoor theatre Centro Venustiano Carranza, under the auspices of the Federal District, but it seemed that the special train was too long for speed and the stations too short for its length, features which, coupled with the sudden illness of one of the members of the party, necessitated several stops, so that the pageant was missed—greatly to the disappointment of the delegation and we feel, also, of our Mexican hosts who had gone to special effort to arrange it for us. Speaking of sickness, however, the crowd was fortunate indeed as only 2 or 3 cases came to notice throughout the 9-day period and these were not directly associated with the trip, which speaks well for the culinary service and care provided on the train and at the various luncheons and festivities. The Pullman cars were occupied as living quarters by all except a few who went chiefly to the Hotel Regis on the Alameda. In fact, not a few occupied the same train berths for 10 to 11 days, i.e., back to St. Louis and New York City.

In order to have a quiet sleeping place in Mexico City the A. P. H. A. Special

was side-tracked into Buena Vista Station and the site proved most satisfactory. Taxies could be obtained for one peso (48 cents, American money) to practically any point in the city, but for all regular meetings and trips some 15 auto-buses were provided each accommodating about 20 persons.

On Monday, November 3, the delegation was taken on a tour of the elaborate new Federal Health Buildings, which are arranged in a horseshoe shape with a central garden, fountain, and pond, and flanked in the rear with a large laboratory building. After the group had been photographed, it repaired to the library where the following program was given:

Address of Welcome. RAFAEL SILVA, M.D., Chief of the Departamento de Salubridad Publica (interpreted by Dr. Miranda).

Reply to Address of Welcome. HUGH S. CUMMING, M.D., Surgeon-General, U. S. Public Health Service, Washington, D. C.

History of Health in Mexico. ULISES VALDEZ, M.D., Secretary General, Departamento de Salubridad Publica (in Spanish).

Local Public Health Work. MIGUEL E. BUSTAMANTE, M.D., Director Public Health Unit, Veracruz, Ver. (in English).

After the addresses of welcome, the ladies of the party, who numbered nearly 100, at Madame Silva's invitation, left in motor cars for a sight-seeing tour of the city. This meant some event too, since Mexico City includes in its official bounds its suburbs, with a total population of about one million souls. About noon the groups met again at the Public Health Buildings and were conveyed in the auto-buses with the escort of the famous motorcycle squad of Mexico City which recently toured the States and also appeared in Hollywood motion pictures. In fact, members of the squad accompanied us on all of our trips, some of which were as much as 45 km. from the city, and we were constantly impressed with the expedition with which things moved. Contrary to the ex-

pectation of some of us, only a few soldiers were seen here and there while taxies of well-known American makes were really safer than in American cities. No traffic lights are seen in Mexico City, but the police stand on small boxes and direct traffic. Talk about being modern—nothing but motor vehicles (outside of bicycles, which are not numerous) are permitted on Mexico streets! Buses, street cars, automobiles and pedestrians keep up a continually changing scene everywhere, the main streets being broad and sunny. We had fine weather for all of our days in the city, which is at an altitude of 2,290 m. (7,444 ft.).

Our first sight-seeing trip was to Xochimilco. On the way out we stopped at the statue of Eduardo Liceaga on which a wreath was placed in his honor by Surgeon-General Cumming in behalf of the delegation, and the ever-present photographers were busy as ever. In fact, Mexican photographers are the most adroit in the world. Almost before you knew it, and indeed before they were dry, mounted photographs were for sale of each and every event and from all positions of vantage.

At Xochimilco a fine luncheon was served under the auspices of the Department of Public Health at the restaurant Las Flores, accompanied by orchestral music and Mexican songs. Dr. Ulises Valdez welcomed the party in Spanish, while Dr. Miranda in a fine flowing voice and an excellent command of English, acted as interpreter. Dr. Cumming responded in English. The party was then taken in small groups on gondolas for a tour of the canals between the tropical "floating islands," peopled and cultivated by Indian natives. Opportunity was also given to inspect the native Indian village.

We were then brought back to attend the reception at Chapultepec Castle, located on a rocky, conical hill

in the city, which was once the palace of Cortez and, before him, of the ancient Aztec rulers. Here each was given an opportunity to shake hands with President and Madame Rubio, a *tout ensemble* picture was made in the esplanade of the Castle, and guides were provided for a tour of the great building with its settings, rich in Maximilian lore, and of times before him. Thereafter the evening was free, and many visited the Alameda and the market district.

On Tuesday morning, November 4, the buses met the party in front of the station for an inspection trip of the buildings of the Federal Department, including the Institute of Hygiene, an infant clinic and maternity institute, and a tuberculosis dispensary. At noon, we left for the "Desert of the Lions," about 30 km. distant and at a considerable elevation, where the ancient Carmelite Monastery, of enormous dimensions, abandoned nearly a century ago, stands concealed in the heavy pine forest in a mountain gorge with its walls, gardens, and subterranean passages still in a fair condition of repair. Luncheon was served here in the open air under the shelter of huge trees and the great garden wall. This was under the auspices of Secretary of Public Works Gral. Juan Andrew Almazan. Dr. Grucman gave the address of welcome which Dr. Miranda interpreted. A chorus of five native male voices and a solo were splendid events.

At 4 P.M. the party left for the return drive to Mexico City. At 8 that evening, the group was invited to attend a concert at the Theatre Hidalgo, given by the Women's Symphony Orchestra. Following this there was a dance at the invitation of the Cosmopolitan Club in Chapultepec Restaurant—a great round, glassed-in building—where caballeros tripped with beautiful señoritas till 1 A.M.

On Wednesday, November 5, at 9:30

A.M., the group again went to the Department of Public Health, where the following scientific papers were read:

Address—B. J. LLOYD, M.D., Pan-American Sanitary Bureau, Washington, D. C.
Safeguarding a City Milk Supply. H. V. CARDONA, D.V.M., Supervisor of Milk Sanitation, Department of Public Health and Welfare, Fort Worth, Tex.

Because of Mrs. Silva's illness, her invitation to the ladies of the party to take a trip to Cuernavaca was cancelled, but independent tours were arranged by the Wells Fargo Company and in private conveyances. A goodly portion of the members made the trip of 75 km. over a splendid highway which soon reached elevations giving a splendid view of Mexico City and less distinctly of the great peaks, Popocatepetl and Iztacchihuatl. Finally the highway topped a mountain pass at 3,008 m. (9,850 ft.), to drop down into a fertile semi-tropical region on the west side of the mountains and into ancient Cuernavaca, where Cortez had his palace and gardens (now open to visitors) and where the summer home of Ex-Ambassador Morrow was visited. Some sought out the cathedral, others the narrow streets of the market and pottery venders; some enjoyed a native luncheon of tortillas stuffed with chicken and aguacates.

At 7 P.M. the doctors of the party were received by the doctors of the National Academy of Medicine, where Surgeon-General Cumming was decorated a Fellow of the National Academy. At 9 P.M. there was a concert of Mexican music and dancing at the Preparatory School given by the Department of the Federal District. Here one also had leisure to inspect the magnificent wood carvings and panels of the interior.

On Thursday morning, motor buses took the delegation to visit the clinic of the Department of Education, where nose, eye, ear, throat and skin diseases

are treated. Some rose early and visited the Cathedral—the largest in America—the National Museum with its great Aztec Calendar Stone and the San Carlos Art Gallery. Next, the party was conveyed to San Juan Teotihuacan, 45 km. distance, the place of the great Toltec Pyramids of the Sun and the Moon, and the lesser "Lights." After visiting the museum here, one walked the "Path of the Dead." Many ascended the Pyramid of the Sun. Some visited the Open-Air Theatre hedged about with tall organ cactuses. Some visited the excavated temple, Ciudadela, and saw the ornately carved Pyramid of Quetzalcoatl (the Feathered Serpent). Luncheon was served in the Grotto Restaurant, a great cavernous subterranean space well lighted by natural rocky apertures on one side. This luncheon was under the auspices of the Secretary of Public Education, whose representative greeted the party, and where Dr. Cumming replied on behalf of the delegation. Dr. Valdez spoke eloquently, and his speech was interpreted by Dr. Miranda. It was indeed a strange sight to see some 300 people seated at long tables in the Grotto with two Mexican orchestras occupying upper ledges, and the frequent explosions of the photographers' flash powders; nor will one soon forget the fine native songs of the entertainers.

On both the going and return trips to the Pyramids, the mists of Lake Tetzoco were seen, blending with the

distant sky. Stops were made at the Shrine of Guadalupe Hidalgo. On the outward trip some ascended the long stairway of the Convent Hill.

After dinner, served on the train—our meals were served in the two Pullman dining cars attached to the train—a Mexican band in grey uniforms filed through the station to the train platform while the delegation crowded the observation car and the various car entrances to hear "The Swallows," the Mexican farewell song, the strains of which accompanied our "Adios" to Mexico City as the train slowly pulled out into the darkness.

We were not long enroute before we discovered that Dr. Pruneda had delivered to the train innumerable gift packages, one for each member of the delegation, containing souvenirs of Mexican art. During the homeward trip an interested representative of the group in each car collected contributions for gifts for Dr. Silva and Dr. Miranda. The delegation also requested the Executive Board of the Association to draw up suitable resolutions expressing its appreciation of the hospitality of the Mexican officials, and their tireless efforts which had made the visit to Mexico City such an outstanding success.

At 5 P.M., on November 8, the special train reached Fort Worth, and members of the delegation went their separate ways, most of them carrying home a good tan from Mexican sunshine.

NEW MEMBERS

Health Officers Section

- T. A. Callahan, Bel Air, Md., Assistant Deputy Health Officer
 D. St. C. Campbell, La Plata, Md., Deputy State Health Officer
 Eugene O. Chimene, M.D., Austin, Tex., Assistant Health Officer
 John W. Copeland, M.D., Auburn, N. Y., Health Officer
 Mordy A. Elstein, M.D., Lovington, New Mex., County Health Officer
 Alva C. Hamblin, M.D., Brooksville, Fla., District Medical Officer, State Board of Health
 Harvey B. Henry, M.D., Luling, Tex., City Health Officer
 J. A. Jackson, M.D., Vernon, Ala., County Health Officer
 A. C. Jones, M.D., Kingsville, Tex., City and County Health Officer
 Sidney L. Kuposky, Dorchester, Mass. (Assoc.)
 James D. Lowry, M.D., Fort Dodge, Ia., Member, State Board of Health
 William J. MacDonald, M.D., Wellsburg, W. Va., County Health Officer
 Bradford Massey, M.D., Pocomoke City, Md., Deputy State Health Officer
 Crispin B. Matha, Ann Arbor, Mich. (Assoc.)
 Rollin E. May, M.D., Lexington, Ky., Director, Fayette County Health Dept.
 Charles W. McDonald, DeFuniak Springs, Fla., District Medical Officer
 A. M. Morris, Langhorne, Pa., Health Officer
 O. C. Pierson, St. Paul, Minn., Director, Division of Administration, State Board of Health
 Edward L. Russell, M.D., Santa Ana, Calif., Deputy Health Officer, Orange County Health Dept.
 William J. Sandidge, M.D., Shreveport, La., Director, Caddo Parish Health Unit
 A. C. Shamblin, M.D., Cartersville, Ga., Commr. of Health, Bartow County
 Hugh H. Shaw, M.D., Utica, N. Y., Health Officer
 W. H. Sory, M.D., Jacksonville, Tex., City Health Officer
 F. K. Soukup, M.D., Port-au-Prince, Haiti, Public Health Officer, National Public Health Service
 I. C. Sumner, M.D., Chatom, Ala., County Health Officer
 J. W. Wallace, M.D., Douglas, Ga., Health Commissioner
 Edward M. Williams, M.D., Oskaloosa, Ia., Health Officer

Vital Statistics Section

- Maria Doyle, Phoenix, Ariz., Vital Statistics Dept. Bookkeeper (Assoc.)
 Paris R. Eastman, New York, N. Y., with Metropolitan Life Insurance Co.
 Mrs. Anna Galbraith, Phoenix, Ariz., Statistician, State Board of Health
 Mrs. Naomi P. Goodin, Jefferson City, Mo., Statistician, State Board of Health
 Mrs. Marie B. Strassburger, Sacramento, Calif., Registrar of Vital Statistics

Laboratory Section

- Harry E. Braun, M.D., Houston, Tex., Pathologist, Jefferson Davis Hospital
 Cooper Brougher, Selma, Ala., Director, State Branch Laboratory
 Elizabeth C. Brown, St. Louis, Mo., City Dept. of Health Laboratory
 Eleanor Bullock, Albuquerque, N. Mex., Bacteriologist, State Public Health Laboratory
 H. L. Burger, Lawrence, Kans., City Bacteriologist
 Fred Cadham, M.D., Winnipeg, Man., Bacteriologist, Manitoba Medical College
 Gertrude E. Connor, Lansing, Mich., Bacteriologist
 Jane B. Currie, Tallahassee, Fla., Director, State Board of Health Laboratory
 Margaret M. Diehm, Ph.D., Philadelphia, Pa., Instructor in Bacteriology
 Martha O. Eckford, Sc.D., Columbus, Miss., Professor of Bacteriology and Hygiene, State College for Women
 Wilson D. Elliott, Ottumwa, Ia., Milk Inspector, Bacteriologist for Water Works
 Richard V. Goslaw, Cedar Grove, N. J., Laboratory Technician, Dept. of Health
 Walter T. Harrison, Washington, D. C., Surgeon, U. S. Public Health Service, National Institute of Health
 D. E. Hasley, Detroit, Mich., Instructor
 Harriet C. Hollon, Grand Rapids, Mich., Bacteriologist, Dept. of Health
 Roberta Lovely, Montclair, N. J., Bacteriologist, Dept. of Health
 Margaret MacLanahan, Butte, Mont. (Assoc.)
 Ora M. Mills, Houghton, Mich., Assistant Director of Laboratories, State Dept. of Health
 Mary P. Moffett, Elmhurst, Pa. (Assoc.)
 William B. Sarles, Ames, Ia., Instructor in Dairy Bacteriology, Iowa State College
 Morris F. Shaffer, Cambridge, Mass., Instructor, Massachusetts Institute of Technology
 Pauline K. Smith, Ann Arbor, Mich. (Assoc.)

Beulah Teter, Monrovia, Calif., Bacteriologist,
City Health Dept. Laboratories

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

CONVALESCENT SERUM CLINIC

EDGAR E. MARTMER, M. D.

Detroit Department of Health, Detroit, Mich.

THE Convalescent Serum Clinic of the Detroit Department of Health was opened January 17, 1928, at the Herman Kiefer Hospital. Its purpose is to provide convalescent serums for passive immunization and therapeutic treatment of the acute communicable diseases.

The immediate emergency which led to its establishment was the measles epidemic of 1927 and 1928. This epidemic was rather severe, and since the only reliable method of preventing or modifying the disease is the use of human serum from convalescents, it was decided to attempt to provide the physicians of Detroit with sufficient serum to passively immunize infants and children under 4 years of age who had not had a previous attack, and who had been in direct contact with a case of measles.

With the success of the work with measles serum, the activities of the clinic were extended to include convalescent serums for scarlet fever, mumps, chicken pox, whooping cough, and poliomyelitis. Small amounts of serum were also collected for experimental use in the treatment and prophylaxis of influenza, meningococcic meningitis and pneumonia.

With the announcement of the availability of these serums there has been an increase in the demand for them, which has resulted in a rapid growth of the clinic. During the first

year 327 donors were used. In 1929 the number rose to 458, while in the first half of 1930 there were 460 donors, which will make the total for the year over 900.

There has been a marked increase in the demand for convalescent scarlet fever serum, there having been produced in 1928, 8,212 c.c. of scarlet fever serum; in 1929, 29,925 c.c. At the present rate we will produce approximately 48,000 c.c. in 1930. Table I shows the amounts of serum we have produced and distributed up to July 1, 1930.

TABLE I

Disease	Total			
	No. of Donors	C.c. of Blood	C.c. of Serum	Doses
Scarlet Fever	566	121,400	59,137	10,887
Measles	162	73,920	40,129	4,912
Whooping Cough	72	16,265	7,987	624
Chicken-pox	74	15,885	8,855	564
Poliomyelitis	63	13,360	6,697	191
Normal	62	11,950	5,608	181
Mumps	39	6,305	3,490	391
Influenza	8	1,900	910	10
Meningococcic Carriers	8	1,735	825	
Meningococcic Meningitis	4	980	460	
Total	1246	271,865	133,198	17,760

It is not the purpose of this paper to show the value of convalescent blood serums in the prevention and treatment of the acute communicable diseases, but rather to show that it is possible to ob-

tain a large number of donors and a sufficiency to make the supply of convalescent serums available to all who require it.

The personnel of the clinic consists of 1 part-time physician, 2 full-time nurses, and 1 technician.

The first step in the operating and maintaining of a clinic depends upon having available the names and addresses of all cases of communicable disease, and this is made possible by the use of the files of the Communicable Disease Division of the Department of Health. As every case of communicable disease is released from quarantine, a slip is sent by the registrar to the Communicable Disease Division, notifying them of the release of the case. This information is in turn forwarded to the Serum Clinic. The names are filed and used as necessary. A letter is sent explaining the work of the Serum Clinic, and asking recovered cases, if they are physically fit, to write, telephone or make a personal call to discuss the question of giving serum. As a report is received, a definite appointment is made, and donors are requested not to take any food in any form for at least 3 hours preceding their visit to the clinic. They are assured at this time that sufficient blood will not be taken to inconvenience them in any way.

When they arrive at the clinic, history is taken, both personal and communicable disease. The personal history includes the name, address, telephone number, age, sex, weight, and color, also the date of recovery from the communicable disease for which they are donating blood, and the name of the physician who attended at the time of illness.

The blood is taken by introducing a 16 gauge sterile needle into the vein of the forearm, and from 100-400 c.c. of blood is drawn into sterile flasks. After the blood is taken, the donors

are paid \$10 in cash at once, and asked if they are willing to return. If they are willing, and the blood is satisfactory, a form letter is mailed to them in 2 weeks, and once a month thereafter for one year, making further appointments.

The blood which has been withdrawn is immediately placed in the icebox, and the following morning the flasks are centrifuged and the clear serum withdrawn. A sample of the serum is tested by the Kahn and Wassermann tests, and, if the reports are negative, this serum is then pooled with several other quantities of the same type of serum. Carbolic acid in a proportion of 0.4 per cent is added, and the serum is then tested for sterility.

A second sample is typed and the results recorded so that donors of serums for various communicable diseases are available according to type for transfusion purposes.

After being proved sterile, it is bottled in containers in quantities of 7.5 c.c. for prophylactic use, and 30 c.c. for therapeutic use, these amounts having been found to be the most satisfactory. The serum is then incubated for a week and again tested for sterility. If the packages are sterile, they are labeled and given a batch number, so that we are able to trace any given dose of serum. Samples are also kept for future study.

When a physician desires convalescent serum for either prophylactic or therapeutic use, he can obtain it at the Department of Health, the only requirement being that he furnish a report as to its value. The value of the serum has been reported by other members of this department, and further studies are under way.^{1,2}

Domestic Employees in Newark—In Newark an ordinance took effect September 1, 1930, requiring that all domestic servants should have a physical examination either at the hands of a licensed physician or, without charge, by the Department of Health. The Health Department issues a certificate which is good for a period of 6 months, indicating that the domestic has been found free from tuberculosis and any other contagious or communicable disease. The regulations of the department require that all restaurant and kitchen employees, where food is cooked or served, must come to the Health Department Clinic for examination. An exception is made for a few large department stores and insurance companies where complete clinic facilities are available. All other food handlers, including: grocers, milk dealers, confectioners, bakers, butchers, soda dispensers, etc., and domestic employees may be examined by private physicians or at the Health Department clinics. It is stated that 90 per cent of these examinations are made at the clinics. When made by a private physician, the examination must be reported on blanks provided by the Department of Health.

—C. V. Craster, Health Officer.

Clinical Conferences on Communicable Diseases—In the belief that ultimate progress in preventive medicine must depend on the degree of interest evidenced by the practicing physician, the Detroit Department of Health for the past 2 years has conducted its toxin-antitoxin campaign in direct collaboration with the private physician, rather than by means of public health clinics. The success of this project, in stimulating general interest in preventive medicine among the profession, was so gratifying that the idea has been further extended. Aside from accomplishing specific prophylaxis, the most important method by which the private physician

can aid in limiting communicable disease consists in early diagnosis of actual infections which arise in his practice. The number of contacts is thereby limited and early treatment favors a lower case fatality.

The contact of the Department of Health with the medical profession has largely been by means of lectures, literature and general educational measures. In an attempt to reach the physician more intimately, and to offer something of more direct relation to the practical problems of his profession, the Department of Health and the Public Health Committee of the Wayne County Medical Society last year inaugurated a series of clinical conferences on communicable diseases. Practical problems in early diagnosis and demonstration of preventive and therapeutic measures were presented by means of case histories and the demonstration of patients. These conferences were so successful, both from the standpoint of attendance and interest, that the committee arranged for a second series which started October 29, 1930. In response to numerous requests this activity has been extended to include all physicians in the southeastern part of the state and all others in Michigan who may find it possible to attend. Health officers are particularly invited to these clinics.—Detroit Department of Health.

Epidemic Jaundice—During the month of October, 1929, the attention of the Health Officer and School Physician was drawn to the appearance of jaundice among the school children. Eight cases were found during the month, and on October 24, 1929, two specimens of urine were taken to Dr. Flexner, at the Rockefeller Institute for Medical Research. On October 25, 1929, Dr. Flexner reported finding moving spirochetæ under the dark field microscope and that guinea pigs had been inoculated. On November 4,

1929, Dr. Flexner reported that the guinea pigs had died and showed the lesions and symptoms of infection with *Leptospira icthohemorrhagiae*, and that the carrier of the disease was the rat. Sporadic cases occurred during the winter months to the middle of April, 1930, amounting to 17 cases.

Clinically the symptoms noted were malaise and nausea, followed by vomiting and jaundice. The amount of

jaundice varied in intensity in different individuals. The temperatures were low in most all cases and the disease lasted about 2 weeks.

The first 4 cases occurred about a half a mile from the Town Dump and in a general way the remainder of the cases spread along the water course near which the dump is situated.—Lawrence E. Poole, M.D., Fairfield, Conn.

MANGANESE IN RIVER WATER AND ITS REMOVAL

PERKINS BOYNTON, F. A. P. H. A.

Chemist in Charge, Clarksburg Water Board, Clarksburg, W. Va.

DURING the last 10 years or so, in the section of the country including West Virginia and other soft-coal producing states, manganese has been found in increasing quantities in the river waters. Previously it was not a problem in water purification nor was it recognized apart from the other contents of a water removed by filtration or other treatment.

The writer left West Virginia in 1917, after operating the Clarksburg Filter Plant for 5 years, beginning about a year after the plant was started in 1910. In these 6 or 7 years, the sand, originally a nearly white bar sand, had grown a little darker, as was to be expected from the passage of coagulated, settled water. Upon his return to Clarksburg in 1924, he found that the filter sand was black in the beds, and of a dark brown color when dry. Soon after a brownish black deposit was discovered on the bowl of the Wallace & Tiernan Suction Type Chlorinator, which had been installed to feed the

filtered water within the last 3 years previous to that time. Chemical examination showed that the discoloration in the filter sand and the deposit in the chlorinator was due to manganese. Examination of the river and treated waters proved the presence of manganese in both, to the extent of 0.1–0.2 part per million. This amount was sufficient to darken the sand through continuous operation, that in the filtered water evidently being taken up from the sand grains.

The treatment at the Clarksburg Plant now consists of the addition of alum and lime, the latter fed to the raw water to increase alkalinity and to the filtered water to remove free CO_2 . Softening is not usually attempted.

During the present drought, when the water was considerably harder than usual, it was decided to use up a supply of soda ash that was on hand. Although the plant is not equipped to soften water, 50 per cent of hardening constituents was removed—all sulphates,

alkalinity running nearly nil.

Frequent tests for manganese in both the raw and treated water began to show that while the manganese in the river water was increasing in the filtered water it had nearly disappeared. The run with soda ash was soon over, and as the continued drought caused the hardness and also the free CO_2 to increase, hydrated lime was added beyond the amount necessary to make up the deficiency in alkalinity or to a phenolphthalein reaction of 7–10 (pH 8.3), with the result that, whereas the manganese in the river water has now

reached 2.0–2.4 parts, that in the water sent to the city is 0.0–0.1 part. This high manganese content is accompanied by 300 parts hardness, 30 parts free CO_2 and alkalinity 0.0 to slightly acid. Iron is only 0.1 part.

The renewal of all sand and gravel in the 8 beds is contemplated this fall and it will be interesting to note the appearance of the sand from time to time and to check by analysis for manganese, if the above mentioned scheme of operation is followed at such times as the manganese is high or the necessary coagulation schedule will permit.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Suicide Among Negroes in the United States—Although negroes have a homicide death rate over eight times that of the white population, they comparatively rarely take their own lives. In 1927, the latest year for which general population statistics are available, there were only 373 suicides among negroes out of a total of 14,096 in the Registration States of the United States. This number gives a death rate of 4.1 per 100,000 population for negroes as compared with a rate of 14.1 for the whites. In other words, almost three and one-half times as many whites as negroes commit suicide.

But although relatively few negroes commit suicide, it is interesting to find that among the industrial policy holders of the Metropolitan Life Insurance Company the divergence between the suicide rates for white and colored people is not nearly so great as it is in the country at large. In 1927, the

standardized death rates were respectively 11.1 and 6.2 per 100,000 among the white and colored policy holders. The white rate was, in short, less than double the colored. Not only was the rate for insured white persons lower than in the general population, but the rate for insured negroes was distinctly higher.

At first sight, it appears rather disconcerting that 156 of the 373 negro suicides, or 42 per cent of the total, were in the insured group, although they compose only about one-quarter of the negro population of the country. But, upon analysis, we find two very good reasons for this discrepancy.

First, the negro policy holders of the Metropolitan are almost exclusively city dwellers. It is well known that throughout the world suicide is much more frequent in urban centers than in rural areas. Among the negroes as well as the whites, we find the same

differential in favor of those living in rural districts. In the Registration States of the United States in 1927, the urban rate was 9.6 per 100,000 for the colored as contrasted with 2.4 in the country districts. Nowhere is there more conclusive evidence of the favorable factors in rural living as regards suicide than in our southern states, for we find that suicide death rates for southern states, as a whole, are very low; whereas for the white population of southern cities they are strikingly high.

The second item which explains the higher suicide rates of negro policy holders is that those insured in the Metropolitan reside, for the most part, in the cities of the North. In fact, over two-thirds of the insured are found in northern cities. It is not surprising to find, therefore, that of the 156 suicides in the year, 118 or 75 per cent took place in northern cities. There is clearly a marked difference in status between negroes in the North and in the South. The unfavorable health situation of those who have migrated from the rural areas of the South to the great industrial centers of the North has been pointed out. Suicide rates would likewise seem to be affected by the disorganization which accompanies such movements of population. Thus, among negro industrial policy holders, in addition to the greater strain which urban life exerts, there is added the adverse effect on health and stability of a change from the South to the North. Our studies point to the conclusion that the mortality of the negro is better in the South and especially better in the rural districts of the southern states. This analysis of suicide frequency only adds to the strength of that conviction and explains why the suicide rate for insured negroes is so much higher than for the negro population as a whole.—Met. Life Ins. Co. *Stat. Bull.*, 11: 4-5 (Sept.), 1930.

MARRIAGE AND DIVORCE, 1929

Alabama—There were 29,430 marriages performed in Alabama during the year 1929, as compared with 28,853 in 1928, representing an increase of 577 or 2.0 per cent. In 1916, there were 25,453 marriages performed.

During the year 1929 there were 3,589 divorces granted in the state, as compared with 3,817 in 1928, representing a decrease of 228 or 6.0 per cent. In 1916 there were 2,265 divorces granted. There were 10 marriages annulled in 1929 as compared with 11 in 1928.

The number of marriages per 1,000 of the population was 11.3 in 1929, as against 11.2 in 1928; and the number of divorces per 1,000 of the population was 1.38 in 1929, as against 1.48 in 1928.

Oklahoma—Oklahoma reported an increase of 25.7 per cent in the number of marriages in 1929 over 1928, the actual number performed being 35,789 and 28,472 respectively.

During the year 1929 there were 8,252 divorces granted in the state, as compared with 7,762 in 1928, representing an increase of 490 or 6.3 per cent. In 1916, there were 3,693 divorces granted. There were 164 marriages annulled in 1929, as compared with 172 in 1928.

The number of marriages per 1,000 of the population was 14.7 in 1929, as against 11.7 in 1928; and the number of divorces per 1,000 of the population was 3.40 in 1929, as against 3.20 in 1928.

Kentucky—There were 30,474 marriages performed in Kentucky during the year 1929, as compared with 29,065 in 1928, representing an increase of 1,409 or 4.8 per cent.

During the year 1929 there were 4,592 divorces granted in the state, as compared with 4,610 in 1928, representing a decrease of 18 or 0.4 per cent. There were 8 marriages annulled in 1929, as compared with 13 in 1928.

The number of marriages per 1,000 of the population was 11.7 in 1929, as against 11.2 in 1928; and the number of divorces per 1,000 of the population was 1.76 in 1929, as against 1.78 in 1928.

Kansas—There was an increase of 6.9 per cent in the number of marriages performed in Kansas during 1929 over 1928; the actual numbers were 21,041 in 1929 and 19,679 in 1928.

During 1929, 4,127 divorces were granted, representing an increase of 1.1 per cent over 1928. There were 18 marriages annulled in 1929 and 28 in 1928.

The marriage rate per 1,000 population in 1929 was 11.2 against 10.6 in 1928; the number of divorces per 1,000 population was 2.20 in 1929, against 2.19 in 1928.

Mississippi—The Department of Commerce announces that, according to the returns received, there were 31,495 marriages performed in Mississippi during the year 1929, as compared with 30,263 in 1928, representing an increase of 1,232 or 4.1 per cent.

During the year 1929 there were 3,159 divorces granted in the state, as compared with 3,007 in 1928, representing an increase of 152 or 5.1 per cent. There were 7 marriages annulled in 1929, as compared with 3 in 1928.

The number of marriages in Mississippi per 1,000 of the population was 17.6 in 1929, as against 16.9 in 1928, and the number of divorces per 1,000 of the population was 1.76 in 1929, as against 1.68 in 1928.—U. S. Census Bureau, Preliminary Report.

Air Travel Fatality Statistics—

The Actuarial Society of America has published a report on aviation statistics which shows that travel by airplane is becoming safer, because the death rate among passengers is gradually decreasing. The report points out that there is not so much danger of accidents to

passengers riding with pilots with 400 or more hours of experience in the air as with pilots with less than such a number of hours' experience.

The death rate among pilots holding a license of the transport type was 79 per 1,000 for aviators having less than 400 hours of flying while the rate was only 29 per 1,000, or 63 per cent less, among those with at least 400 hours in the air.

While the passenger death rate on railroads in 1929 was approximately 1 per 300,000,000 passenger miles, the fatality rate in airway travel was about 1 per 1,250,000 passenger miles, or more than 200 times as hazardous as railway passenger service. The death rate of aviation passengers from January, 1927, through March, 1930, was 1 per 5,000 persons carried on scheduled air lines.

The number of miles covered by aircraft has an important bearing on the death rate among passengers. The records showed that in non-scheduled commercial flying the passenger fatality rate was about 2 per 100,000 persons carried, or about one-tenth of the mortality experienced in scheduled flying.

The experience of the U. S. Army and Navy pilots showed a death rate much lower for the year ending June 30, 1929, than did the best class of commercial aviators. The death rate of commissioned airplane pilots in the Army was 8 per 1,000 and in the Navy 10 per 1,000. The annual average for the last three years was 13 per 1,000 in the Army and 21 in the Navy.—*Canad. Insurance*, 35: 4 (Aug. 26), 1930.

MORTALITY STATISTICS, 1929

Idaho—The Department of Commerce announces that there were 4,075 deaths in Idaho during 1929 as compared with 4,177 in 1928.

The comparatively few causes of death which showed noticeable increases in 1929 as compared with 1928 were

meningococcus meningitis, which caused more than twice as many deaths, measles, cancer, diseases of heart, and cerebral hemorrhage and softening.

The principal decrease is in deaths from influenza (295 to 163), which alone more than offsets the decrease from all causes; other diseases which caused fewer deaths in 1929 than in 1928 were tuberculosis all forms, pneumonia all forms, diarrhea and enteritis under 2 years, and nephritis. Deaths from suicide and homicide also decreased considerably in 1929, and among accidental causes there was a fair decline in deaths from automobile accidents.

Colorado—There were 12,874 deaths in Colorado during 1929 as compared with 14,077 in 1928.

There was a decrease in the number of deaths in 1929 as compared with 1928 due principally to the lesser number of deaths from influenza and pneumonia. In addition, decreases were reported in the following causes: measles, scarlet fever, whooping cough, diabetes mellitus, diseases of the heart, and nephritis. The number of deaths from tuberculosis (all forms) has decreased continuously from 1926 to 1929.

Among the causes of deaths for which increases are reported are typhoid and paratyphoid fever, and diarrhea and enteritis of children. Deaths from homicide increased from 61 in 1928 to 90 in 1929.

The increase in the number of deaths due to accidental and unspecified external causes was due principally to automobile accidents, though increases were also reported in the number of drownings, accidental falls, mine accidents, railroad and street car accidents.

South Carolina—South Carolina has reported 23,053 deaths during 1929 as compared with 24,427 in 1928.

The most pronounced decrease in deaths in 1929 as compared with 1928 was for measles (from 299 to 4), and

next in importance was that from typhoid and paratyphoid fever, which also showed a remarkable and steady decline from 1926; other notable decreases from 1928 were from dysentery, diarrhea and enteritis under 2 years, pneumonia all forms; tuberculosis all forms, cancer, and congenital malformations and diseases of early infancy; pellagra, also, showed a slight decline, although it ranked among the highest eight causes of death in 1929, when there were 943 deaths as compared with 563 in 1926.

Generally considered, the increases in deaths were comparatively slight, and were shown most noticeably for whooping cough, influenza, diseases of the heart, and cirrhosis of the liver.

Deaths from accidental causes increased from 1,095 in 1928 to 1,161 in 1929, but this increase was much more than balanced by the increase in deaths from automobile accidents (from 251 to 350).

North Carolina—There were 36,919 deaths in North Carolina during 1929 as compared with 36,150 in 1928.

Practically all of the diseases which caused increases in the number of deaths in 1929 were also responsible for a greater mortality in the two years preceding. The causes for which this is true are scarlet fever, whooping cough, diphtheria, influenza, cancer and other malignant tumors, pellagra, diabetes mellitus, cerebral hemorrhage and softening, diseases of the heart, bronchitis, hernia, intestinal obstruction, nephritis, puerperal causes other than puerperal septicemia, suicide, homicide, and all kinds of accidents.

These continuous increases to some extent were offset by continuous decreases for the last 3 years in typhoid and paratyphoid fever, smallpox, measles, cirrhosis of the liver, and railroad accidents.

Most notable decreases from 1928 to 1929 appeared for measles, from 515

deaths to 20, and for diarrhea and enteritis, under 2 years, from 1,284 to 973.

Increases in deaths from 1928 were shown for whooping cough, tuberculosis all forms, diseases of the heart, nephritis, cerebral hemorrhage and softening, and influenza; this last cause increased from 1,567 to 2,304. Suicide and homicide also caused more deaths in 1929 than in 1928.

Deaths from accidents decreased from 1928 to 1929, the greatest reduction in number showing for burns and railroad accidents. The largest increases in deaths were those from shooting, falls, and automobile accidents, the last having mounted steadily and noticeably since 1926.

West Virginia—There were 18,128 deaths in West Virginia during 1929 as compared with 17,507 in 1928.

Marked increases are for whooping

cough, which almost quadrupled the deaths of 1929 from this cause over 1928, and influenza and dysentery, which practically doubled their mortality. These three causes were responsible primarily for the increase in the total deaths although less marked increases are shown for measles, diseases of the heart, pneumonia (all forms), and diarrhea and enteritis (under 2 years).

Decreases even though general were notable in scarlet fever, acute anterior poliomyelitis, tuberculosis (all forms), cancer and other malignant tumors, diabetes mellitus, nephritis, and homicide.

Among accidental deaths, decreases in 1929 were shown for drowning and shooting but these were nearly balanced by the increase in deaths from automobile accidents.—U. S. Department of Commerce. Bureau of the Census. *Provisional Summary: 1929.*

LARGE DEMAND FOR FREE SERVICE IN HOSPITALS

NON-MUNICIPAL hospitals, dependent on voluntary contributions for support in order to provide free care for the sick poor, are having one of the hardest seasons in many years. Homer Wickenden, General Director of the United Hospital Fund, comprising 57 such hospitals in New York and Brooklyn, states that already a 10 per cent increase in the demand for free service has been noted in the hospitals, and that on the average a patient enters one of the 57 United Hospitals or its outpatient department every 30 seconds, and every 12 minutes an ambulance answers an emergency call. This demand

for free treatment is attributed largely to the current business depression, the lack of employment, the exhaustion of savings accounts, and inability to pay even in part for hospital care.

OUTDOOR RELIEF AGENCIES IN NEW YORK CITY

THE people of New York City contribute nearly \$14,000,000 a year for the work of their "outdoor relief" agencies—organizations giving assistance to persons in their own homes. This is disclosed by a study of the income and expenditure of all local welfare agencies over the 17 years of 1910 through 1926 just completed by the Welfare Council of New York City.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

Iron Hydroxide Prevents Mosquito Breeding—Observations by G. L. R. Hancock, in Uganda, record the antagonistic effect of flocculent ferric hydroxide upon mosquito breeding and discover other deterrents of the Anophelines. Senior-White showed that the presence of an oily scum and flocculent masses of iron hydroxide are associated with the absence of Anopheline larvae.

Natural waters were tested with the reagent of equal parts of concentrated hydrochloric acid and potassium ferrocyanide. A swamp showing between 10 and 20 p.p.m. of iron hydroxide (calculated as Fe^3) gave negative Anopheline records. A tin of red soil was put into a water hole containing a large number of *A. gambiae*. The red soil raised the iron content of the well from 5 to 15 p.p.m., two larvae were found; a later observation, when the water showed 10 p.p.m. of ferric iron, revealed no mosquito larvae.

Another swamp containing flocculent iron hydroxide harbored *Culex* but no Anophelines. In a third swamp, not dominated by the sedgy plants Cyperaceae but containing iron hydroxide, only one Anopheline larva was found.

The observations suggest that a high concentration of iron, or some factor with it, is unsuitable for Anophelines, and indicate the possibility of controlling mosquito breeding by the addition of iron, perhaps in the form of red soils containing iron. The action of iron on plankton will obviously require study.

An oily scum which showed few bacteria proved to be composed chiefly of iron hydroxide. There are other iri-

descent oily scums of similar appearance associated with various organisms and inorganic substances. The influence of the flora and its correlation with the composition of the soil and water, as well as the rôle of phytoplankton, will need much study. Most of the swamps in which a large species of Cyperaceae is dominant appear to contain much flocculent red iron hydroxide precipitate and have yielded no Anophelines. J. Omer Cooper is of the opinion that the female mosquito does not exercise a great amount of discrimination but that the larvae fail to survive more from biological than mineral factors.

These observations suggest that mosquitoes may not be found breeding in pools in red clay or other iron-bearing soils, and that such earths added to ponds in gray loams may prevent the development of mosquito larvae. American investigations are needed.

Anopheline larvae occurred only rarely in association with shrimps along the lake shore. G. E. Hutchison stated that in South Africa places suitable for mosquitoes are often unsuitable for predacious water bugs, represented in America by such insects as the waterboatman, Notonectidae. Hancock observed that the small fish attacked the mosquito larvae only when the latter were in motion.—G. L. R. Hancock. *Bul. de la Soc. Royal Entomologique d'Egypte*, 1930. Abstr. H. B. Wood.

Two Years' Study and Practical Use of Crank Case Waste Oil as a Mosquito Larvicide—An account is given of experiments and field observations showing that crank case oil can be

efficiently used against mosquito larvae. The oil almost always requires straining, and apparatus for doing this is described. It does not in itself spread on water, but may be made to do so by the addition of a spreader such as tar acid (containing 25 per cent cresylic acid) or by adjusting the specific gravity of the oil to 32 or 34° Be. by the addition of light petroleum distillates.

Of these, one of the most satisfactory was found to be a waste product obtained from "varnolene," which is used as a solvent in the varnish industry, etc. It is a low boiling petroleum distillate and possesses the following specifications: Be. gravity 46.8°; flash point 96° F. closed cup; 160° F. open cup; boiling range 300–417° F. Like tar acid, it is itself highly toxic to mosquito larvae, whereas crank case oil is not. The lasting quality of the oil mixture is from 2 to 4 weeks, or twice as long as that of fuel oil, and the cost is about half that of the latter.

A method of calculating the amounts of the two oils to be mixed that are required to obtain a mixture of a given specific gravity is described.—J. P. Peterson and J. M. Ginsburg. *Proc. 16th Ann. Mtg. New Jersey Mosquito Exterm. Assn.*, Atlantic City, 1929, pp. 92–101. (From *Review of Applied Entomology*, Dec. 1929.) From *Pub. Health Eng. Abstr.*, Apr. 5, 1930. Abstr. V. M. Ehlers.

Deratization of Milan—It was decided that on a given day the deratization program should be undertaken simultaneously by the owners of buildings throughout the city.

Zinc phosphate (30 per cent solution in oil) was used as the active ingredient for the deratization of sewers, canals, public buildings, dumps, etc. For the deratization of dwellings, use was made of products which are less toxic to human beings (squill, *adonis vernalis*, *chelidonium* and *cynoglossum*). A solu-

tion of these active ingredients was furnished by the municipality at cost (5 lire for 50 baits).

On receiving the toxic solution, the householders were given a receipt on which printed requests were made for information regarding the number of baits devoured, the number of dead rats collected, and the presence of living rats following deratization. These cards were to be returned to (sanitary) inspectors.

Proprietors of factories, hotels, stores, etc., were left free to select their own measures of deratization but were required to report on the methods used.

The deratization was declared obligatory in all buildings including those where rats had never been observed. There are 22,170 buildings in Milan, covering a (estimated) surface of 6,000,000 square meters (exclusive of courtyards, gardens, etc.). It is estimated that one bait should be placed for each 2 square meters of surface. Actually, provision was made for the preparation of 4,500,000 baits.

It is estimated that only 2 per cent of the rats killed were found on the surface of the ground, and that 20 per cent of the baits set out were devoured. On this basis the number of rats killed was several hundred thousand.

The campaign is being continued, efforts now being directed toward the rat-proofing of buildings.—Georges Tron. *Rev. Hyg. Med. Prev.*, 51: 745–9. From *Pub. Health Eng. Abstr.*, Apr. 5, 1930. Abstr. Emery J. Theriault.

Digestion of Activated Sludge—The city of Pomona has a very ingenious way of conserving the cost of sewage treatment. A 20-year contract was made with the Northside Water Company of Walnut, Calif., to use the effluent from the activated sludge plant. The company agreed to pay one-half cent per inch-hour from October to

April, and one cent per hour for the remaining 6 months. All of this water is subsequently sold for irrigation purposes. In addition to this revenue Pomona charges two small cities for treating their sewage, sells water from a paper mill, and leases the sewer farm. The revenue comes from the following sources:

Sale of effluent (disposal plant)	\$4,669
Sale of sludge	414

A study was made of pumping sludge from the activated sludge plant into the digestion chamber of the Imhoff tank. Experience showed this was not a satisfactory method. Sludge came up in the flowing-through chambers, completely destroying the action of the Imhoff tank. Greatly improved results were obtained by diluting the activated sludge with raw sewage, influent, to the Imhoff tank.

The author of this article mainly discusses costs of operation, and makes a plea for conservation of sewage effluent for irrigation purposes.—F. H. Froehde. *Calif. Sewage Works J.*, 2: 1, 1929, pp. 82–87. From *Pub. Health Eng. Abstr.*, Apr. 12, 1930. Abstr. M. S. Foreman.

Chlorination of Water—A skillful and careful review of the existing knowledge of the practice of water purification, both in America and Europe, and of its hygienic significance. This is supplemented by the results of well planned sets of experiments by the staffs of the Central Public Health Laboratory and of the Water Supply Bureau on the dosage and period of contact necessary for disinfection with chlorine and on the taste resulting from various chlorine dosages applied to a typical dune water. The taste experi-

ments show how widely different individuals, and even the same individual at different times, may vary in capacity to detect low chlorine dosages (less than 0.1 p.p.m.). Applications to swimming pools and sewage are included. The references to the literature are valuable.—A. Masink. *Government (Holland) Water Supply, Bu. Bull. No. 5*, Apr., 1924. From *Pub. Health Eng. Abstr.*, May 3, 1930. Abstr. Frank Hannan.

Experimental Sewage Treatment Work in Europe—In Europe, and particularly in Germany, a great deal of experimental work on sewage treatment is in progress. Activated sludge treatment using the submerged contact aerators, with mechanical paddles in combination with compressed air, is being tried by many cities. Phases of the work receiving particular attention are: The rotation of sludge to hasten sludge digestion and increase gas production; heating the digesting sludge and the collection of gases. In Great Britain a great deal of work is being done on re-aeration of activated sludge. The city of Paris is carrying on experimental work to determine the type of activated sludge plant to be constructed in the future.

Brief descriptions are given of eight interesting plants in Germany, three in Great Britain and one in France. The city of Berlin is constructing a 48 m.g.d. plant which will be operated on a large scale experimental basis.—G. P. Edwards. *Water Works & Sewer.*, 77, 3 (Mar.), 1930, pp. 89–92. From *Pub. Health Eng. Abstr.*, May 10, 1930. Abstr. J. B. Harrington.

Can Tastes and Odors be Removed from Highly Polluted Waters?—Data are presented to show that highly polluted water, i.e., 10 to 20 thousand bacteria per c.c., can be made sterile and entirely free from ob-

jectionable tastes at an estimate of from \$2.00 to \$5.00 per million gallons, exclusive of the cost of clarification.

Baylis believes that the use of ammonia and potassium permanganate for taste prevention is limited. Activated carbon is recommended for dechlorination and taste removal. The author's opinion is that super-chlorination followed by dechlorination with active carbon will produce the ideal testing water.—John R. Baylis. *Water Works Eng.*, 83, 4 (Feb. 12), 1930, pp. 227-228 and 236. From *Pub. Health Eng. Abstr.*, May 17, 1930. Abstr. A. C. Janzig.

A Recent Development in Lime Water Softening—This article describes a method of reducing carbonate hardness of water by lime softening to the theoretical or approximately to the theoretical limit. The process comprises adding to the water sufficient lime (CaO or Ca.OH_2), to combine with the free and half-bound carbon dioxide and to precipitate the magnesium hydroxide. Considerable lime (25 to 50 p.p.m.) in excess of that theoretically required to replace the magnesium must be added to convert the magnesium salts in the water to magnesium hydroxide. This leaves excess lime or caustic alkalinity in the water. After partial settling the excess lime is neutralized with carbon dioxide, then calcium carbonate, water softening sludge or other inert finely divided material is mixed with the water, after which settling or filtration takes place.

Laboratory experiments at the Columbus water softening and purification works indicate that results far more satisfactory than by the present method may be obtained, that the process will not require close supervision and that it will dispense with filtration difficulties and produce water with perfect chemical balance.—Charles P. Hoover. *Water Works & Sewer.*, 77, 3 (Mar.),

1930, pp. 103-104. From *Pub. Health Eng. Abstr.*, May 17, 1930. Abstr. J. B. Harrington.

Water Service in Holland—The present development of public water supplies in Holland is described with much valuable detail. The history is briefly outlined. The peculiarities of Holland, geologically and hydrologically, are explained. A few of the leading features of the paper follow, but those interested in the history and development of water service would do well to possess themselves of the original.

Of the 7.4 millions of inhabitants in January, 1926, 4.6 are served by 111 public water supplies, of which 80 (72 per cent) are publicly, and 31 (28 per cent) privately, owned. Of the 390 towns and communes served, 45 depend on surface sources, 110 on dune water, 228 on other ground water; the remaining 8 on combinations of these.

Nearly one-half of the country lies below the one metre contour line (above mean sea level at Amsterdam) and would of course be inundated at every high tide and by every flood in the rivers but for the dunes and dykes. A result of the peculiar conditions is that under all the low area except in the dune district water is encountered quite near the surface the salt in which exceeds 400 p.p.m., the limit for acceptable drinking water. Suitable drinking water is therefore scarce over large districts and rural public supplies have been established on a large scale. For instance, the Province of North Holland has 96 communes combined in one large undertaking; the Leeuwarden District supply embraces 12 communes; the S. Beveland Island supply, 24 communes; Tholen, 7; North-west Brabant, 24; South Lunburg, 18.

The 4.6 millions of persons supplied in 1925 used 150 million cu. m. of water; or an average of 89 litres per capita daily, a remarkably low figure.

The average consumption in the eight largest cities varied from 116 litres in Rotterdam to 53 in Haarlem.

The Amsterdam waterworks, the first in Holland, was constructed by English engineers in the year 1853. The Government Water Supply Bureau dates from 1913. The functions are described. On its files are the data of over 18,000 boreholes; over 30,000 soil samples; and about 8,500 water analyses. The composition of four typical waters, those of Rotterdam, Amsterdam, Utrecht and Heerenveen, are given with some detail. Marked improvement in the typhoid situation has resulted, notably in the ten districts, from the introduction of reliable drinking water.

The paper concludes with a discussion of water tower architecture, with illustrations of three desirable models. Two maps and seven graphs are given; also two figures illustrative of equilibrium conditions between fresh and salt ground water, first thoroughly worked out by Herzberg at Nordnervy in 1901, and later by Pennink, a former director of the Amsterdam waterworks. The original discovery of the important governing principle which generally goes by Herzberg's name is claimed by the Dutch military engineer Yhybon in the year 1889.—F. A. Liefcrinck. *Wasserkraft u. Wasserwirtschaft*, 1927, Nos. 10, 11, 13, and 14. From *Pub. Health Eng. Abstr.*, May 3, 1930. Abstr. Frank Hannan.

Oil Exclusion and Removal—Exclusion of grease and light oils from sewer systems is a problem that has received very little consideration, and particularly from the designers of sewer

systems. The grease problem at Los Angeles is quite a difficult one on account of the usual grease wastes, viz., preparation of foods and soapy effluent from laundries, these combined with the wastes from petroleum products, and the waste from a large number of garages.

It has been estimated that the one million people connected to the Los Angeles sewer system contribute 22 tons of grease per day. Practically all of this grease comes from individual house connections. Grease traps, properly maintained, have been suggested as a possible remedy to exclude grease.

Laundries are particularly objectionable because of the slow deposit of thin layers of oily material on the inner surface of pipes. This material accumulates and hardens and is difficult to remove. It has been observed that when laundries are located along large sewers little trouble is experienced, due to high dilutions.

Periodically, large quantities of black oil appear at the ocean screening plant. This oil is very detrimental to sewer screens, causing blinding, and can be removed only by steam. A city ordinance prohibits the wasting of oil in the sewer, but it is a difficult problem to enforce it.

A very dangerous situation is produced by the discharging of gasoline and other light oils into the sewer. Explosions have occurred recently where 30 manhole covers have been blown as high as 25 feet, due to explosive gases. The city is combating this problem by use of a gas detector.—F. A. Batty. *Calif. Sewage Works J.*, 2: 1, 1929, pp. 78–81. From *Pub. Health Eng. Abstr.*, Apr. 12, 1930. Abstr. M. S. Foreman.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M. D., PH. D., AND LEONARD GREENBURG,
M. D., PH. D.

The Health of the Worker of Today—After half-a-century's operation of the Public Health Service Acts the longevity of the race has increased 10 years (British Isles). The war came and instead of the results improving the condition of the working classes, the reverse has been the case. We find ourselves an overtaxed people, carrying an increasing burden of unemployment. We have not tackled the problem of regaining our lost markets diligently as have France and Belgium who now enjoy more prosperity and less unemployment.

The Controller of the Insurance Department of the Ministry of Health, Sir Walter Kinnear, reports that in a group of 500,000 insured persons he found, on comparing the experience of 1927 with the year of 1921, that in 1927 the claims of male members had risen by 41 per cent, those of unmarried women by 60, and those of married women by 106 per cent. In 1921, 14 out of every 100 men claimed sickness benefit; in 1927 the proportion had risen to 23. Among unmarried women the respective proportions were 12 and 21, and among married women 19 and 38. One hardly sees why, with all the efforts which have been made to improve the health of the community, claims of illness should have increased by 60 to 100 per cent within the space of 6 years. It is a fact also that the claims are out of all proportion to the increase in unemployment. Alderman H. J. Blake-way also states that within the last 30 years the average duration of sickness has increased from $16\frac{1}{2}$ days to 28, and this without there being any

marked percentage increase in the number of claimants. Of 2,260 cases submitted to the Medical Referees under the National Insurance Act, 1,034 were at once cleared off the funds of the society. This circumstance of itself suggests the necessity of the exercise of greater care in furnishing and repeating medical certificates of unfitness.

The author next discusses the apparent increase of disability in various industries such as cotton weaving, coal mining, cutlery, etc. Among coal miners nystagmus has considerably increased in the last three decades. Since it has now been found that the malady attacks men working in brightly illuminated mines, there is clearly something more required to cause it than defective illumination, as proclaimed by the late Professor Snell, of Sheffield. Dr. Robson of Cardiff regarded carbon monoxide as the cause, but several analyses have shown this gas to be absent. It is now suggested that it might be of microbic origin. It is interesting to note that 25 per cent of the miners affected with nystagmus do not know that they are the subjects of it.

Formerly a high death rate of comparatively young men occurred in the Sheffield cutlery trades from pulmonary disease and tuberculosis. Likewise, in the pottery trades and the manufacture of lead products. These have now lost to a great extent their evil name and we can therefore claim that industrial hygiene and preventive medicine have not only averted a considerable amount of probable suffering, but have warded off death. Among ship builders within the last 15 years the longevity of the

men has increased 5 years—from 53 to 58.2 years.

In summary, while conditions have materially improved in a half century's time, the one circumstance which stands out prominently and calls for special comment is the lengthened duration of sickness and convalescence.—Sir Thomas Oliver, *J. State Med.*, 38, 8: 454-463 (Aug.), 1930.—E. R. H.

Cokemen and By-Product Workers—Their Complaints and Maladies—Coking of coal goes back as far as 1590 when a patent was granted to John Thornborough, a Dean of York. The original "bee-hive" ovens have now been replaced by "retort" and "by-product" ovens. In the first condenser, tar becomes deposited from the fumes passing from the ovens and, in the second, the ammoniacal liquor is caught. In a further scrubbing benzene is removed. When the remaining material is distilled, the tar, having yielded up fuel oil, becomes pitch. Ammonium sulphate is made by adding sulphuric acid. Further by-products can be obtained such as toluol, naphthalene, pyridine and motor spirit (benzol).

There are employed at coke ovens and by-product works in England and Wales 15,000 men. For the past several years the impression has prevailed that these men suffer disproportionately from stomach troubles, while they are also prone to rheumatism, lumbago, skin eruptions, and warts—the latter frequently taking a malignant turn. The gastritis reported begins at any age and at any period of service and is severe enough to cause the men to lay off, when remissions in the stomach trouble occur. The trouble appears toxic and is accompanied with a sense of fatigue which is out of proportion to muscular work performed. Stomach ulcers ensue in a considerable number of men. They have a sallow complexion and lose considerably in weight. The skin affec-

tions occur on the backs of the hands and forearms, scrotum and penis, also on the brow and eyelids. Bronchial catarrh is common, as might be anticipated from the exposure to heat and cold.

Twenty years ago, Sir Thomas Legge drew attention to the fact that blast furnace tar and pitch did not possess the same cancer producing qualities as those from coal tar. The pitch obtained from coke ovens and gas works and used for making briquettes is said to be the cause of more than one-half of the notifiable cases of cancer in Great Britain. Drs. Bridge and Henry found that, between 1920 and 1927, of 163 cases of cancer occurring in briquette workers, 11 per cent were located on the scrotum, 72.2 per cent on the head, arms, etc., while in 103 cases in tar distillers the malady showed itself in 39.8 per cent in the scrotum, and 37 per cent on the head, limbs, etc., and in men employed in gas works the disease was located on the scrotum in 47.3 per cent, and on the head and elsewhere in 23.6 per cent.

The particular points in the course of transit of the material where the men apparently suffer in health more than at other points are the top-oven men, the hydraulic mains men, the valve men, and the men who break up the solid pitch—these are all liable to adverse influence by dust, heat, and fumes.—Sir Thomas Oliver, *A Report by The National Union of Cokemen and By-Product Workers, Red Hill Villa, Durham, England*, 8 pp., Apr. 16, 1930.—E. R. H.

Outbursts of Carbon Dioxide in Mines—The disaster in which 150 men were suffocated in a Silesian mine has just been reported. The accident was apparently due to the penetration into a mass of disintegrated coal charged with carbon dioxide which then filled all the workings. Professor J. S. Hal-

dane in a letter to the *Times* points out that while such outbursts of carbon dioxide are unknown in Great Britain, they were described more than 30 years ago in the Gard district of France and have since occurred in Silesian and other coal fields.

In one instance the gas and coal dust shot high into the air and for a long time discharged like a volcano. Being heavier than air it came back, spread along the ground like water, and reached a village a kilometer away where it suffocated fowls and dogs, but the level at this distance was too low to kill human beings.

J. I. Graham, Mining Research Laboratory, University of Birmingham, has shown that coal in the presence of even a moderate pressure of gas will absorb a large volume of it from which enormous outbursts may occur. In British mines several lives have been lost through sudden outbursts of methane from disintegrated coal, but these are not so dangerous as outbursts of carbon dioxide.—London Letter, *J. A. M. A.*, 95, 8: 605 (Aug. 23), 1930.—E. R. H.

Glasses for Protecting the Eye from Glare—The federal specifications for the protection of eyes of industrial workers from injurious radiation specify that "shade No. 3, filter lenses are intended for glare of reflected sunlight, from snow, water, roadbeds, roofs, sand, etc." The mean transmission of visible light through a shade 3 glass is 13.9 per cent. The specification requires a fairly high absorption of ultra-violet and infra-red rays, which means that the color of the glass is greenish.

The next lighter shade is 2, with a maximum transmission of 60 per cent, but there is no provision in the Safety Code for the use of such a light shade. This is partly owing to the fact that no chances are being taken of possible injury, with attendant legal complications

regarding compensation for alleged injury. Personal experience on mountain elevations, etc., in the West indicates that a shade 3 glass is necessary to relieve the discomfort from glare.

The author has been confronted with the problem of newly exploited eye glasses that come and go like the style of hats and dresses. Amethyst-colored glasses transmit almost as much of the ultra-violet and visible rays as the white crown glass generally used in spectacles. While attractive in appearance and a good sales proposition, the author could not learn of any real advantage over the ordinary spectacle glass.

The nearly colorless glasses put on the market in recent years are of two general classes such as (1) "Softlite" and "Velvetlite" which are transparent to ultra-violet rays to practically the same extent as white crown spectacle lens, and (2) "Cruxite" and "Vio-pake"—all of these glasses have practically the same transmission as common spectacle glasses for the infra-red rays. They transmit some 85–90 per cent of the visible rays as compared to 91 per cent in white crown lenses when perfectly clean, and some 85–90 per cent as commonly worn. They offer no protection from the glare of bright light as defined in the beginning of the paper.

Most reflecting surfaces, except snow and water, absorb a much greater amount of ultra-violet than the visible rays. Hence, we are concerned mainly with the glare of visible light and not the presence of ultra-violet radiation.

Aside from style, the purpose of prescribing these glasses is not clear. Cases are few in which it is important to reduce the intensity of average daylight. When, however, one is near ultra-violet ray lamps and sparks from induction coils dark glasses should be worn to protect the eyes from ultra-violet radiation. Unlike the sun, these artificial sources are in the direct line

of vision and unavoidably shine into the eyes.—W. W. Coblentz, *J. A. M. A.*, 90, 8: 593–594 (Aug. 23), 1930.—E. R. H.

Annual Report of the South African Institute for Medical Research for 1929—This Report is, like its predecessors, of real interest. Studies have been continued on the subjects of plague, hay fever, tuberculosis, ancylostomiasis, the typing of pneumococci and meningococci. The Department of Industrial Hygiene has continued its studies on the subject of silicosis, chiefly under the direction of Dr. Mavrocordato. Elaborate and most interesting studies on dental caries are enumerated, which should yield some most valuable information on this subject. The transmission of plague from rodent to rodent has been demonstrated in the plague research laboratory and, finally, detailed investigations on the subject of cancer have been pursued in the pathological research laboratory.

The report of the Routine Division is most interesting and enumerates the vast amount of work which this laboratory has performed, an amount too great to detail at this point.

This most interesting and valuable

report closes with a list of 22 papers published by various members of the staff.—South African Institute for Medical Research, *Annual Report*, year ending Dec. 31, 1929.—L. G.

Sulphur Dioxide in the Air at the Pittsburgh Experiment Station of the U. S. Bureau of Mines—Three hundred and four determinations of the sulphur dioxide content of the outdoor air at the Pittsburgh Experiment Station of the U. S. Bureau of Mines were made between August 11, 1927 and 1928. An average amount of 0.16 p.p.m. was found. The maximum amount found, 1.1 p.p.m., existed on 2 days, and less than 1/10 p.p.m. (the minimum detectable amount) was observed on 141 days. The most frequently encountered value lay between 0.1 and 0.4 p.p.m., an amount found on 134 days. The direction of the wind was not found to be a significant factor in altering the concentration of sulphur dioxide in the air: The concentration was found to decrease with higher wind velocities and to be high on foggy or smoky days.—E. G. Meiter and C. E. Traubert, Department of Commerce, U. S. Bureau of Mines, R. I. 3005, June, 1930.—L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Effects of Ingestion of Tartrate or Sodium Aluminum Sulphate Baking Powder upon Growth, Reproduction and Kidney Structure in the Rat—Many investigators have studied the adsorption of aluminum by the animal body after the ingestion of its salts and the effects on digestion and health of aluminum baking powders. This paper reports the results of sodium aluminum sulphate-calcium acid phosphate baking powder and cream of tartar baking powders on white rats, 30–50 gm. weight at the beginning of the experiment.

Commercial baking powders representing the two types were used. These were first mixed with water until reaction took place, heated, dried, ground, and mixed with food in amounts equivalent to what would ordinarily be contained in biscuits made according to recipes advocated by the manufacturers. The largest dose of S.A.S. baking powder represented 4 mg. aluminum per rat per day.

The ingestion of S.A.S. baking powders in amounts up to a dosage represented by 2 per cent of the diet and the ingestion of tartrate baking powders in amounts up to 4 per cent of the diet showed no marked injurious effects. Six generations were raised on rations containing approximately 2 per cent of S.A.S. baking powder for the first and second generations and 4 per cent for the succeeding generations. The rate of reproduction, the number of young successfully weaned and the rate of growth showed that the ration containing this baking powder is equal to similar rations containing none.

Microscopic examination of the kidneys of the animals fed according to the manner described in this paper failed to show that the length of time during which the feed was consumed or the proportions of the ingredients of the food itself brought about any pathological changes. The kidneys of the rats fed for a period of 21 months on the ration containing 2 per cent S.A.S. baking powder presented no microscopic lesions whereby they could be distinguished from the kidneys of the rats receiving the basic ration containing no baking powder residue.—J. F. Lyman and Ernest Scott, *Am. J. Hyg.*, 12: 271 (July), 1930.

Effects of the Habitual Use of Tartrate and Aluminum Baking Powders upon the Utilization of Food in the Rat—Reference is made to the fact that the literature records only one experiment on the effects of baking powder on the utilization of food and that is the report of the Referee Board of Consulting Scientific Experts, *Bulletin 103*, U. S. Department of Agriculture. This was on human subjects who ingested baking powders containing salts of aluminum over a period of 130 days. When the intake amounted to 200 to 260 mg. of aluminum per day mild catharsis resulted but there was little or no effect on the utilization of food.

In the present experiment, albino rats were fed their respective diets for a period of about 15 months when the effects on digestion were determined. Commercial powders were employed, one a tartaric acid-tartrate type, and

the other sodium aluminum sulphate-calcium acid phosphate.

Powders were moistened, heated, and dried, ground and mixed with an adequate control diet supplemented by cod liver oil. The tartrate residue was mixed with the diet in proportions corresponding to 1 gm. of baking powder to 25 gm. of food, and the S.A.S. residue was mixed so that it represented 1 gm. of baking powder to 53.5 gm. of food. Each proportion represented the amount which would be present on a calorie basis according to recipes of the manufacturers.

The digestion periods were of 10 days, and there were recorded the composition of the diet, food consumption, feces production, and weight of animals. The determination of digestibility coefficients indicated that rats fed over this long period on baking powder residues showed no effects on digestion and no cathartic action was observed.—Ruth M. Kraft, *Am. J. Hyg.*, 12: 283 (July), 1930.

Vitamins in Dried Fruits. II. The Effect of Drying and of Sulphur Dioxide upon the Vitamin A Content of Fruits—A previous report (*A. J. P. H.*, 29: 1053, Sept., 1929) of these investigators on the protective action of sulphur dioxide on vitamin C in peaches led to the conclusion that a similar effect might be found in vitamin A. Reference is made to the recent reports on the destructive effects of sulphur dioxide on the vitamin A in cod liver oil as compared to the same vitamin in butterfat and alfalfa and the varying results of experiments on vitamin A activity in purified carotene crystals which may be explained by the variations in catalytic or oxidative action rather than a fundamental difference in the vitamin.

In the present experiment, California prunes, peaches and apricots were employed. Dried fruits were stored at 0°

and the fresh fruit was ground and frozen. The SO₂ content of dried fruit was determined by the A. O. A. C. method as well as the pH of fresh and rehydrated fruit.

Rats 21 days of age were placed on a vitamin A-free diet supplemented by 0.5 gm. dried yeast per rat per day. The fruit was fed generally in 3 or 4 doses per week and was begun after the appearance of vitamin A deficiency, usually after 25 to 35 days. The fruit-feeding period lasted 56 days. The standard for feeding was the amount of fruit which produced an average weekly gain of 6 to 8 gm.

Tables show the percentage of vitamin A retention calculated on the standard of 100 per cent vitamin A content of fruit. This is based upon the dose of frozen, fresh fruit which permits at least 6 gm. gain for 8 weeks and is regarded as representing 100 per cent vitamin A content of fruit. Similar units were employed for dried fruit calculated to its fresh fruit equivalent, and the ratio between the weights required represents the vitamin retention. On this basis sulphured peaches, both dehydrated and sundried, retained 86 to 100 per cent of vitamin A in the fresh fruit and the unsulphured, sundried fruit about 90 per cent. The unsulphured, dehydrated product apparently lost about 50 per cent.

Yellow peaches were found richer in vitamin A than white varieties and there was a correspondingly less loss with this fruit whether sundried or dehydrated. Sulphured prunes showed somewhat greater retention than the unsulphured and the dehydrated sulphured 50 per cent greater retention than the sundried sulphured prunes. The lye-dipping of prunes apparently was without effect on vitamin A.

Apricots were found especially rich in vitamin A both in the fresh and dried fruit. This appears to be a governing factor in retention which was found to

be somewhat greater in the sulphured product. The vitamin A of apricots is apparently easily affected by drying since only 16 to 51 per cent of the fresh fruit value was retained, but with this loss apricots contain more vitamin A than the best of the peaches and prunes. The unusual richness in vitamin A in apricots is noted in connection with the hemoglobin regeneration effect of dried apricots reported by other investigators. The vitamin A content of apricots compares favorably with the best figures reported for spinach, egg yolk and butter.

Dried prunes and apricots were retested after storage at 0° for 12 to 14 months and results showed practically the same as before storage.—Agnes Fay Morgan and Anna Field, *J. Biol. Chem.*, 88: 9 (Aug.), 1930.

Cystine Deficiency of the Proteins of Garden Peas and of Potatoes—A previous experiment (*J. Nutrition*, 2: 225, 1930) showed that the proteins of garden peas and potatoes were deficient in cystine. Because of the small number of animals used in the potato experiment and the cooking to which the peas were subjected, the experiment was repeated.

The garden peas were shelled, passed through a hand mill, dried at a low temperature and reground. The potatoes (Ohio Red variety) were boiled, peeled, riced, dried at a low temperature, and ground.

Tables are given showing the composition of rations. The experiment on potato proteins involved 8 pairs of rats and on peas, 9 pairs. Tables are given showing the weekly gains.

The experiment showed that the growth-promoting value of the proteins of these two foods is enhanced by the addition of cystine; hence, these protein mixtures are deficient in this amino acid. These experiments failed to support the assumption that the more complete of two rations will be consumed

in larger amounts.—Jessie R. Beadles, Winfred W. Braman, and H. H. Mitchell, *J. Biol. Chem.*, 88: 615 (Sept.), 1930.

Cereals and Mineral Metabolism—Ordinary foods except egg yolk have not been found to be potent in vitamin D. The severity of the experimental rickets used in testing cod liver oil and irradiated products suggests that with a less powerful rachitic diet some of the other foodstuffs might show at least a protective value in rickets.

The present work deals with wheat rations compared to oat rations on rats with adjustment of the calcium phosphorus ration. There were 4 groups in each series, 1 group in which the calcium phosphorus ratio was high, 1 in which it was extremely low, and 2 intermediate in which it approached unity.

Vitamin B was deemed sufficient since the rations both in the wheat and oats contained 60 per cent of cereal. Three per cent of butterfat was used to supply vitamin A. The experiments were conducted over a long period of time and in some instances as much as 135 days.

The results show that in the wheat series the growth on the high calcium phosphorus is relatively poor compared to the growth in the groups where the calcium phosphorus ratio approached unity irrespective of the amount of food consumed. In the low calcium phosphorus group growth was not so good as those in which the ratio approached unity which was better than in the high calcium phosphorus lot.

The rats on oat diet showed a similar relationship but in all cases the growth was not so good as with the comparable wheat group. The conclusion is reached that with mild rachitic rations such as in this experiment wheat contains sufficient vitamin D to protect against rickets and to permit spontaneous healing if sufficient time be given. The oat diet is less effective in spon-

taneous healing. Both experiments indicate the effectiveness of the calcium phosphorus ratio which appears optimum when nearest unity.

Reference is made to recent investigations showing that rolled oats is more rachitic than wheat and that calcium phosphorus retentions were higher on a wheat than on an oat diet. The author ascribes the differences in the wheat and oat diets to differences in variation of vitamin D content.—M. S. Fine, General Foods Corporation, *Cereal Chemistry*, 7: 456 (Sept.), 1930.

Tooth Growth in Experimental Scurvy—In this experiment the normal growth rate of the teeth of guinea pigs was determined. Animals were placed on the Sherman-La Mer basal diet with 1 per cent cod liver oil. During the test the animals were scored by the Sherman method for scurvy and weighed every 5th day.

At the conclusion of the experiment the animals were killed and the lower jaws, ribs, and extremities were studied histologically. The incisor teeth were checked at various levels for determining the degree of scurvy. The vitamin A supplements were contained in diets

of orange juice, tomato juice, turnip greens and mixed green vegetables.

On .5 c.c. of orange juice daily the rate of tooth growth increased and there were slight scorbutic lesions in the incisor roots but no scurvy evident by the Sherman score, which is based on the weight curve plus clinical observations as to pain, hemorrhage, etc. One c.c. of orange juice increased tooth growth but pronounced scurvy was found in the incised teeth. Tooth growth was scarcely increased on 0.5 c.c. orange juice, and advanced scurvy was present contrasted with the Sherman score of moderate scurvy.

Animals on the basal diet alone showed a tooth growth for the first 15 to 20 days which then ceased but recommenced after the administration of 5 c.c. of orange juice daily. By studying the appearance of scorbutic substances in amputated teeth compared to those uncut and subjected to normal chewing strain it was found that the stress is a definite factor in the scorbutic process. Photomicrographs show the changes in the odontoblasts and the formation of osteodentin.—Gilbert Dalldorf and Celia Zall, *J. Exper. Med.*, 52: 57 (July 1), 1930.

PUBLIC HEALTH NURSING

EVA F. MACDOUGALL, R. N.*

A Nursing Program in a County Health Department—At the Conference of Health Officers and Public Health Nurses held at Saratoga Springs, N. Y., in June, Marion Sheahan, R.N., Assistant Director of the Division of Public Health Nursing of the New York State Health Department, in discussing "A Nursing Program in a County Health Department" gave a summary of the purposes of a nursing division in a county health unit:

1. Provide a supervisory service by a well qualified nurse or nurses to:

- (a) Direct the nursing activities of the county health department in order to relieve the county health commissioner of the detail in connection with the work,
- (b) Assist in outlining and maintaining an adequate program of work,
- (c) Aim to correlate the nursing services of the county,
- (d) Aid in placing qualified nurses in the field,
- (e) Introduce new nurses into various fields to insure standard work,
- (f) Outline and conduct staff education on a county-wide basis, offering this service to all nurses no matter by what agency employed,
- (g) Coördinate the nursing work of all agencies so as to utilize it to best advantage in promoting a county-wide health program under the direction of the county department of health,

2. Provide sufficient staff nurses to make service available to areas not covered by existing agencies. Also, offer assistance to local organizations, for example, in the event of communicable disease outbreaks, round-up of preschool children, tuberculin testing of school children, inspection of boarding homes, maternity homes, and similar activities.—

Health News, New York State Department of Health, pp. 147-148, VII, 37: (Sept. 15), 1930.

Pearl McIver, Director of the Missouri State Department of Public Health Nursing, in a paper read before the 1930 Conference of Indiana Health Officers at Fort Wayne in September, made some further points on the relation of the public health nurse to county health work. She said that educational work through individual and group instruction should occupy the largest part of the nurse's time. Rather too often we find a health officer who feels the chief duty of the public health nurse is to tag along with him and wait upon him much as a surgical assistant would in an operating room. "Some public health activities require the combined efforts of physician and nurse, but time is often wasted by too much 'joint work.'"

Westchester County Shows the Way—The Westchester County (N. Y.) Health Department and the Northern Westchester District Nursing Association have worked out a mutually helpful arrangement

... to provide the necessary regulation and instruction for cases of communicable disease in towns served by the association and that are under the direct supervision of the central office of the County Health Department. Local nurses in the association in these towns will visit all reported cases of communicable disease requiring legislation, to give instruction relative to isolation and concurrent disinfection and to post placards as provided by the State Sanitary Code. Epidemiological investigations will continue to be carried on by the County Health Department, which will

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 126 State House Annex, Indianapolis, Ind.

also offer consultation service for diagnosis, when desired.

A similar arrangement has been made with the local nurses in Hastings, Larchmont, Cortlandt and Greenburgh, where there are no local health officers.—

The Link, Westchester County Health Bulletin, 5, 7, p. 3: (Aug.-Sept.), 1930.

Public Health Nurses in a Diphtheria Campaign—An intensive diphtheria campaign was carried on in 2 districts in Detroit by a group of nurses in the Detroit Department of Health from July 2 to September 2. The parents of 23,748 children were interviewed, and 38.25 per cent of these had already had toxin-antitoxin; the nurses prevailed upon the parents of 39.39 per cent of these remaining to have it given.

It is significant to find that the intensive house-to-house canvassing resulted in the immunization of an appreciably larger proportion of younger and more susceptible children than did the general city-wide educational

campaign. For example, only 51.1 per cent of the children given toxin-antitoxin before the intensive work of this summer were under six years of age, while of those protected through the nurses' efforts this summer 67.4 per cent were under six years of age.—

Age Distribution of Children Protected Against Diphtheria, *Weekly Health Review*, City of Detroit Department of Health, Series 11, 38: Sept. 20, 1930.

It seems impossible to find the death rate from diphtheria in the 1-6 inclusive age group, but authorities agree that this is the group that needs toxin-antitoxin most for, as Lee says, "A large number of children have been immunized, but unfortunately most of this work has been done among the school children and very little among the pre-school population. Two-thirds of the deaths from diphtheria occur in the 0-4 age group."—Walter W. Lee, M.D., *Diphtheria, Its Treatment and Prevention*, A. J. P. H., XVIII, 10: 1246 (Oct.), 1928.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Exhibits at Fort Worth—Health railroad cars, educational and technical or commercial exhibits as a whole gave but little evidence that use is being made of what we actually know about the planning and preparation of graphic material. The Harmon prize display of the New York Diphtheria Commission was excellent of its kind, and several educational-commercial displays were colorful and distinctive. Specific suggestions can be offered exhibitors upon request.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

People Who Can't or Won't Read—Five million illiterates—who had "no schooling whatsoever"—reported in the census; one in four million and a half soldiers and sailors who did not show "ability to read and understand newspapers and to write letters." *They cannot read our newspaper articles, pamphlets, folders, leaflets, house organs—not even our posters.* What other means do we use for reaching them? Is it worth while to check up on illiteracy records—in our state or city—to determine where there is special need for unusual efforts to reach such groups?

A Useful Source Book—"Health Education in the Public Schools," by Anne S. Whitney; "Popular Health Education," by Ira V. Hiscock; and "Publicity in Social Work," by Mary Swain Routzahn, appear among 197 topical articles (nearly 50 on phases of public health) in *Social Work Year Book*, a new publication of the Russell Sage Foundation. \$4.00.

Those articles briefly state the history and present status; training requirements and opportunities; developments and events, 1929; and legislation, 1929, supplemented by reading references and descriptions of the interested national organizations. Doubtless the tentative classification of these national agencies, a useful feature, will be done better in the next issue of the *Year Book*. The present listings under health education and publicity include several not primarily concerned with these subjects and omit many others doing as much as most of those listed. A basis for selection is difficult to work out.

Let's Start the Experiment Right—The Committee on Administrative Practice has made another practical and forward-looking contribution. "For experimental use" the committee offers a set of forms for recording departmental activities. We hope those concerned with health education will join in the experiment. We suggest at the start that you consider a few changes.

In the first form—Cumulative Monthly Report—among the nine columns given to "Popular Health Instruction" are two headed "Health plays and motion pictures" and "Attendance." Health plays are *not* accounted for in the *Appraisal Form for City Health Work* on which this report form is based and so that item is out of place in the new record form. Moreover, plays may be considered an oc-

casional and incidental form of popular health education and the least of the forms to be conducted by a city health department.

Another column in this form is headed "Circulation of fixed publications." "Fixed publications" is not used in the *Appraisal Form*, and it is not an accepted term for any specific form of publicity. It would seem better to use words that carry over from some item in the *Appraisal Form*.

In the second blank form now offered—called a Summary of Activities for the Month—there is a heading for "Number of pamphlets distributed" for which there is no corresponding space in the preceding form.

In the introduction to the blank forms it is said of the Summary that "it is easily compiled each month from the Cumulative Report." But in the first form there is that space for the *combined total of plays and motion pictures*, while in the second form the corresponding blank reads "Number of *health films* shown"—that is, in some fashion the health officer will "easily compile" the figure for the number of motion picture showings out of a total made up of motion pictures and plays.

Of much less importance, doubtless, is the upper heading on page 25 of the first form: "Health Classes, Plays and Films." Why there should be this extra heading is not clear.

In neither of the blanks are there spaces for all of the items included in the *Appraisal Form*.

Getting Health Workers to Read About Health Work—The first month 126 magazines were requested—143 the second month—as a result of a mimeographed bulletin, "Selected Articles from Public Health Magazines," prepared by the Los Angeles County Tuberculosis and Health Association (132 West 1st St., Los Angeles), and issued

in the name of that body and of the County Health Department.

This list does not pretend to be a comprehensive index. Its purpose is rather to stimulate interest in current health material among health workers in Los Angeles County by bringing to their attention timely and readable articles.

A mimeographed reply blank is enclosed with every copy of the list. We hope that future issues will refer to this Education and Publicity department, and other departments in the *Journal*. We thank Prof. Ira V. Hiscock for bringing this excellent device to our attention.

How "Old" Is the Reading Public?—Under this title Robert R. Updegraff discusses whither "in our copy, are we over-shooting the mass mind?" The author tells of an especially popular high school textbook on ancient history and how the author of the book explained its popularity.

"Well," said he, "there is a perfectly good reason. That book was intended as a text for boys and girls 13 or 14 years of age. When the manuscript was finished, and before a single line of it was set in type, I paid a boy of 11 to read it and mark every word he did not understand. Then I went through the book and inserted simpler, understandable words or phrases for every word he had marked. Or I rewrote the sentence entirely in the interest of greater simplicity."

Mr. Updegraff tells of his own first published story, "Obvious Adam," which has sold up in the thousands through 15 years.

After the story was finished I went through it page by page, sentence by sentence, methodically challenging every word of more than two syllables. Wherever a shorter, simpler word could be substituted, it was done. The result was rather startling.

Four questions are suggested by the author to be raised before using "big" words:

1. Is there a simpler word that will do?
2. Can it be left out entirely by rewriting

the sentence in simpler form?

3. Will it mean to the reader what it means to me?

4. Will it go through the reader's mind as "just one of those words" or will it actually register something very definite?—

Advertising and Selling, 9 East 38th St., New York, N. Y., Sept. 17, 1930. 25 cents.

Peas, Potatoes, Pumpkins—The following from the *Daily Bulletin*, at Fort Worth, was prompted by program announcements at Fort Worth of various sessions in which all discussion of three, four or five papers in a session was combined after all the papers had been given:

Were you ever in a meeting for the discussion of the technique of successfully raising peas, potatoes and pumpkins—simultaneously?

Peas, potatoes, pumpkins; pumpkins, potatoes, peas; peas . . . what a mental porridge would result!

And what mental confusion must result when three or four papers presented in a convention program are discussed in the same period?

Program committees, please copy.

Headquarters at Fort Worth—For the first time in a number of years there was no Health Education and Publicity Headquarters at the Fort Worth meeting of the A. P. H. A. If acceptable space is provided at Montreal we will try again next October to bring together outstanding examples of health publicity and samples of materials of use to the publicity worker as has been the custom of this department.

"Have You a Book?"—Thus is headed a report in *The Survey* (Oct. 15, 1930) of a checkup of professional and general books and magazines read by social workers in Hartford, Conn.

Is it not worth while to give thought to the professional reading of staff mem-

bers and of all health workers in our city or state? Do we "all have a book"—and therefore do not give other books a chance to contribute to our professional equipment?

We can give details of the Hartford experiment if our readers are interested.

When Editors Fear Their Readers—Even yet some newspapers fear to mention syphilis and gonorrhea in their news columns. Some of the few which carry advertisements of quacks and nostrums will not mention the diseases by name in news articles.

When such a condition exists in a city it is suggested that a tactful man, sympathetic towards the editors' viewpoint, personally discuss the subject with the editors. The caller may go armed with information about what other newspapers and periodicals have done and what has been said on the subject in *Editor & Publisher*, the influential organ of the newspaper world.

Among the material available: the series of advertisements placed in the *Saturday Evening Post* by the American Social Hygiene Association; advertisements in daily papers of the New Jersey and West Virginia State Departments of Health; advertisements in Chicago dailies; discussion in *Journal of Social Hygiene*; discussion in *Editor & Publisher*. Doubtless the American Social Hygiene Association, 370 7th Ave., New York, N. Y., could provide typewritten copies of this matter.

Please report to this department examples of news mention, advertisements or discussion of the subject.

Tests and Checks on Health Education—Every scrap of information about any form of test or check on methods or materials is desired by the editor of this department. Please send in any clue to anything you know about or have read about even of the most informal nature. .

The Challenge to the Publicity Worker—Said President Hoover, in a message addressed to the School of Journalism, University of Missouri:

The greatest challenge to the ingenuity of journalists is to make these things (science, social advance, civic idealism) as interesting to the public as are the more familiar subjects which apparently must be treated in terms of conflict.

Health Books for the Public Library—"The Most Suitable Health Books for the Public Library" are discussed and listed by James A. Tobey and Raymond S. Patterson, in *Library Journal*, 62 West 45th St., New York, N. Y., Nov. 1, 1930. 25 cents.

The first test of a book on such an important topic as human health is its scientific accuracy. There is no room for fads and follies, nor for individualistic medical notions and opinions. The second essential characteristic is readability, together with a practical and reasonable presentation of important facts in an attractive style. A book for serious reading need not be a dull book. It should, moreover, avoid technical language and be clear, concise, and cogent, but thorough, logical, and diverting. There is plenty of romance in this adventure called health, in this drama which is the game of life. The books listed and described comply with the specifications, and others. They are arranged under six divisions, with, of course, an overlapping between them. As an introduction to the general subject, five books have been included under the caption, "The Background of Health." Perusal of these particularly entertaining books will result not only in an absorbing fund of useful information, but also in an adequate conception of the science called public health.

Selections from the copious quantity of books on baby care are conspicuously absent from the list on "Maternal and Child Hygiene." As in the case of the health habits, such material may be readily obtained in numerous reliable pamphlets and books issued by official and voluntary health agencies and by reputable commercial organizations interested in public health.

An Effort to Check Results—How can patients needing medical attention

be brought under treatment? Does popular health education really result in bringing under medical care persons infected with syphilis and gonorrhea?

For some years various types of health publicity have been used to induce persons to seek treatment and it has been assumed that such education has been effective. The results, however, have not been measured nor is there available data to show the value of different types of health propaganda.

Demonstrations are being carried on in New York, Chicago, and Boston with the object of finding out something about the value of various methods and materials used in health propaganda. The Bellevue-Yorkville Health Demonstration, the City Health Department, the New York Tuberculosis and Health Association and the American Social Hygiene Association are sponsoring the New York demonstration which is confined to the Bellevue-Yorkville area. This area is the district between 14th and 64th Streets on the east side of Manhattan, with Fourth Avenue as the western boundary below 42d Street, and Sixth Avenue above.

Lectures, motion pictures, posters, pamphlets in various languages are being used in a wide-spread effort to reach every section of the population. Hospitals, clinics, and doctors are co-operating by supplying the number of their patients under treatment for syphilis and gonorrhea before, during and after the campaign. These figures will give an indication of the value of popular health instruction, the object of which is to bring the infected under treatment. The demonstration will continue about three months, reaching its height in November.

Similar education methods will be employed in the Boston campaign which will occupy a part of several months; while the most intensive part of the Chicago campaign will be limited to one week.—Doris G. Chandler.

Shop Talk and Working Tools—

Such will be found in every issue of the *News Bulletin* of the Social Work Publicity Council, 130 East 22d St., New York, N. Y. *Sample free.* The October, 1930, issue discusses "Come and See" visits and how to make more of them; mentions that the S. W. P. C. prize newspaper story, "Health and Charm at End of Rainbow by 15,000 Girls," was reprinted in the September issue of *Everybody's Health*, St. Paul (10 cents); that Association of Community Chests and Councils, 420 Lexington Ave., New York, N. Y., has albums of photographs by Hine, Myers & Moss (prints can be bought at modest prices); starts a discussion of how to secure bequests; explains that a few dates are open for convention or local visits by the collection of prize award publicity specimens; and describes numerous publicity specimens and ideas.

"Telling the Public"—Old truths are re-stated by Edith M. Ross, a county nurse (*Survey*, 112 East 19th St., New York, N. Y., Oct. 15, 1930. 30 cents):

Are most of us eye- or ear-minded? Do we notice more, do we remember better, what we see or what we hear? From my own experience, first as a county nurse, then in state work, I find that people remember better what I say if they can see at the same time something allied to the subject of my talk. Charts, especially in speaking to adults, always help. Tack maps are nearly always fascinating. There is something concrete, vital about them—something that takes away the intangibility of mere figures and brings facts home to us. Our public is far more hungry for information than we imagine. But we must be careful not to repel it by trying to feed it dull, dry, lifeless facts.

The staff nurses of the Minnesota Public Health Association, when they make school inspections, use a small cloth dog or monkey or a "Felix" cat to arouse the interest of the younger children. Into any of these, which consist of a head and forelegs, we run

the fingers of one hand. Then we get the children to ask it questions such as: "How many glasses of milk do you drink?" or "What time do you go to bed?" And the dog or cat or monkey, as the case may be, waves one paw slowly to indicate the number of glasses of milk he consumes or the hour at which he retires. He shows them, too, how he washes behind his ears, how he brushes his teeth. There are few health habits which these toy animals cannot help us expound. And when I return the following year, I find that what Coco, my monkey, or Milko, my dog, has told them has not been forgotten.

TRY ONE OF THESE?

"For 700 years traders have tried their cleverest advertising stunts on merchants who come annually to the Leipzig fair."—Caption under a photograph of a man with a big clock on his head. Probably makes the hands go round—or the alarm to ring. Try "Now is the time for a health examination(?)"

New displays of health pamphlets may be found in the lobby of the Health Department which is entered from Third Street. These include pamphlets about measles, cancer, smallpox, tuberculosis, diphtheria, heart disease, whooping cough, goiter, influenza, tonsils and adenoids, common colds, and the latest numbers of this Health Department's bulletins. In addition, there will be found in the Health Department up-to-date files of health magazines and health books which the Public Library does not keep. Pamphlets are free to individuals or in quantities to organizations. Books and magazines may be borrowed by signing up for them.

—Racine, Wis., Department of Health.

An effective "testimonial"—a letter of thanks from a client—is reproduced in facsimile, with the street address and the signature crossed out by pen—on a folder going with an appeal letter from the New York Diet Kitchen Association, 578 Madison Avenue, New York, N. Y.

The latest health tabloid is "North Harlem Photo News," issued by the Diphtheria Prevention Commission of the Department of Health, New York, N. Y. Includes "Harlem First to Have New Health Center," "Children, Rich

and Poor, Often Suffer from Lack of Right Food Says Expert," "Magic Rings of History," "The Inquiring Reporter" (who asks: Do you save money throughout the year for your summer vacation?), "Voice of the People," etc. 17 pictures. Much display type. *Free*.

The Diphtheria Prevention Commission and the Bellevue-Yorkville Health Demonstration have amply illustrated the possibilities in making health information and suggestions *look interesting*.

Some cities—or states—might try the idea in a 2-page form to reduce the cost.

MAGAZINE ARTICLES

"The Church and Birth Control," by Right Rev. Charles Fiske. *Atlantic*. Nov., 1930. "The Lambeth Conference marks a great departure."

"Doctor and Patient." *Nation*. Nov. 5, 1930. "The remedy . . . lies in the reorganization of the industry."

"Looking for Trouble," by Ruth F. Wadsworth, M.D. *Colliers*. Nov. 8, 1930. "Looking for trouble in order to avoid it, otherwise known as periodic health examinations. . . ."

"Mothers in Danger," by Ruth F. Wadsworth. *Colliers*. July 5, 1930.

"The Patient Looks 'at Doctors.'" Anonymous. *Harpers*. Nov., 1930.

"To Be Or Not To Be?" by Louis I. Dublin. *Harpers*. Sept., 1930. "The facts about suicide."

"Who Pays the Price?" by Frances Sage Bradley. *Mountain Life and Work*, Berea, Ky. Oct., 1930. 30 cents. A story presentation of need for maternity and visiting nurse services.

LANGUAGE

"Odds Bodkins" in *Advertising & Selling* quotes from Clyde Fitch:

This time you have realized exactly what I was striving for—honest simplicity of language and unconventional treatment of conventional situations.

BOOKS AND REPORTS

The First Year of Life—By Charlotte Buhler. Translated from the German by Pearl Greenberg and Rowena Ripin. New York: The John Day Company, 1930. 281 pp. Price, \$3.50.

The translation of the researches of Prof. Charlotte Buhler and her associates upon the behavior reactions of the infant throughout its first year has made available to English readers the most elaborate and extended study of this age period that has yet appeared. It involves the continuous day and night observation for 24 hours of 5 children in each month of life and the meticulous recording of their behavior. The investigation was carried on for the most part in 1926 at the Reception Home for Children in Vienna.

Part 1 is devoted to a discussion of the negative, positive and spontaneous reactions of developing infants; the protocols carefully describing every movement and expression for a number of typical days are given in extenso. The time occupied by sleep, dozing, in taking food, in negative reaction, in quiet waking, in negative and impulsive movements, is graphically charted. An inventory of the observed behavior for each month of the first year is given.

In part 2, a series of tests is suggested which are intended to ascertain how the child develops in physical and mental control of himself, in social relationships and in the manipulation of materials. As a basis for the tests the inventory of behavior above referred to was used. The materials needed for these tests and the method of application are carefully described for each month of age.

The author is confident that these various tests may corroborate or re-

verse a casual judgment. Children thought to be retarded or accelerated in development were found to be so only apparently. Children socially responsive are usually thought to be abnormally bright, when complete testing indicates that they may be slow in manipulating material.

In a series of children retested after 6 months, the results obtained agreed with those in the first examination.

The book covers a difficult field. It is an attempt to estimate the potential capacity of the young infant. There is not infrequently a lack of clearness in expression due possibly to the effort of the translators to follow the original text too closely.

If the most important study of mankind is man, it is desirable that this study begin at the earliest possible age. This is the objective of these painstaking observations.

J. H. MASON KNOX, JR.

Industrial Hygiene for Schools—By Jesse Feiring Williams and Delbert Oberteuffer. New York: McGraw-Hill, 1930. 271 pp. Price, \$2.00.

This small volume has been designed for the purpose of indicating health problems in modern industry and for pointing out health guides for general living to young men and women who are about to enter industrial life. That this has been achieved there is no doubt, for a large number of the problems of industry are discussed, at least, briefly. Perhaps the greatest defect of the book lies in the fact that many of the discussions are so brief that the content has suffered "by compression"; the sections devoted to the subjects of ventilation, dusts and poisons are examples of this. The chief virtue of the

book lies in its scope and the many excellent illustrations which serve to enhance interest in an already very readable volume.

LEONARD GREENBURG

Dictionary of Biological Equivalents. German-English—By Ernest Artschwager. Baltimore: Williams & Wilkins, 1930. 239 pp. Price, \$4.50.

This dictionary gives the equivalent in English of about 15,000 German scientific terms of general use in the biological sciences. It is somewhat more complete in the botanical, pathological, and anatomical fields than in the zoological and physiological. The plates illustrate a few morphological details of plants and animals. Useful lists of common German abbreviations, of irregular verbs, of metrical equivalents, of important reference books, and of related dictionaries supplement the verbal ones.

The utility of this work lies in the fact that the smaller German-English dictionaries rarely contain the definitions of the compounded scientific words and the assembled definitions of the elements do not always reveal the meaning of the compound. This compilation is thus a time-saver and a convenience for the biologist.

C. A. KOFOID

Artificial Sunlight—Combining Radiation for Health with Light for Vision—By M. Luckiesh, D.Sc. New York: Van Nostrand, 1930. 254 pp. Price, \$3.75.

In this book, the author, who is recognized as an authority upon the subject of light, has brought together in readable fashion a great variety of data concerning the effects of radiant energy and the physics of the subject. A perusal of this work should temper irresponsible and enthusiastic imagination, which too often has been the basis

of claims made for the benefits of light in the ultra-violet region.

A real justification for an authoritative reference book of this sort is offered in the following quotation: "Quackery flourishes in the twilight zone of knowledge. Likewise something closely akin to it develops during the same period—practices based upon unquestionable sincerity but lacking adequate knowledge of the nature or of the effects of the alleged remedy." With so complete and so readable a source book as is furnished by Dr. Luckiesh there now seems no longer any excuse for exuberant and unjustified expectations regarding the value of light.

The author presents logical reasons for his expectation that a new type of lamp described extensively in this book will supply a combination of radiations for health and for vision. If this new lamp is as meretorious as is the large body of convincing scientific experimental data adduced in support of its design, it may indeed be the introduction to an era in which "artificial sunlight can be more than a safe and unfailing substitute for a midday, midsummer sunlight during the entire year."

The book is attractively printed and arranged and reasonably well indexed.

JOHN W. M. BUNKER

Trauma, Disease, Compensation—A Handbook of Their Medico-Legal Relations—By A. J. Fraser, M.D. Philadelphia: F. A. Davis Company, 1930. 506 pp. Price, \$6.50.

The tendency of present-day compensation acts is undoubtedly to make more liberal provision for accidents and diseases occurring in industry. Increased knowledge of compensation laws and their provisions on the part of workers and lawyers has had the effect of bringing suits for compensation of all kinds which have never before been brought into court.

The effect of these forces has been

to increase the number of cases of all kinds and the types of these cases continue to present new, interesting, and difficult problems for solution by the medical expert and the compensation commissioner.

The volume at hand is essentially a compilation of compensation decisions and medical opinions concerning injuries and diseases of all the organ systems of the body. The final chapter is devoted to rating schedules for the apportionment of permanent disability.

The effects of trauma may be localized or general. They may be manifest in the traumatized region or at some more distant point. The effects may be immediate or remote in time, or they may be continuous in nature and form a chain of events, the nature of which and relation to the original injury it may be the duty of the medical expert to discover.

The present volume presents a most valuable discussion of these relationships in a manner which is readable, informative and accurate. Compensation attorneys, medical experts and compensation commissioners should find this an excellent addition to their libraries.

LEONARD GREENBURG

A Practical Medical Dictionary—*By Thomas Lathrop Stedman, M.D. (11th rev. ed.) Ill. New York: Wood, 1930. 1222 pp. Price, \$7.50.*

There is little to say about a dictionary which has gone through 11 editions, all of which have been favorably received. Dr. Stedman's work has made its place on merit. The latest edition has maintained the high standard of those preceding it. One must concede to the author of a dictionary the right of judgment as to the inclusion of certain words. Practically all dictionaries, for the sake of completeness, include many words which are useless to the vast majority of readers. There are some omissions from this volume

which we consider unfortunate, though they do not seriously affect its general value. The omitted definitions might well have taken the place of some which are given.

The volume ends with appendices giving a list of drugs, their doses and uses, weights and measures, temperature and barometric scales, chemical elements, pathogenic organisms and pathogenic microparasites. The printing is excellent, the type clear, and the illustrations good. The book can be entirely recommended.

M. P. RAVENEL

Tobacco—*By Walter L. Mendenhall, M.D. Cambridge: Harvard University Press, 1930. 69 pp. Price, \$1.00.*

This is one of the Harvard Health Talks, No. 17, delivered as a popular Sunday afternoon lecture. It gives many facts concerning tobacco and the effects of its use, useful tables of the amount of nicotine contained in many brands of cigarettes, and analyses of the composition of cigarette smoke.

It begins in a tone of levity which does not impress a serious reader favorably. It ends by leaving the matter entirely to the judgment of the individual. Certain important studies are not mentioned. On the whole, it is a fair statement of facts as far as known, but contains some senseless quotations from extremists on both sides which have no scientific value.

M. P. RAVENEL

Science in the Kitchen. The Selection, Care and Service of Foods—*Pittsburgh: Mellon Institute, 1930. 82 pp. Price, \$.60.*

This booklet contains much helpful information written in language which housekeepers generally can understand. In the section "Intelligent Purchasing of Foods" the biological value of proteins is referred to without explanation

as to its meaning, but perhaps this will stimulate study. The author's method of discussing the calorie is especially good. A possible criticism in the section "Good Meals for the Young Home Maker" is that too many unusual and expensive foods are recommended. On the whole it is one of the best popular discussions of foods which the writer has seen.

E. V. McCOLLUM

Introduction to Mental Hygiene—
By Ernest R. Groves and Phyllis Blanchard. New York: Henry Holt, 1930. 467 pp. Price, \$4.00.

Not being a specialist in mental hygiene, the writer has undertaken to review this book with some hesitation, in spite of an interest in the subject which has grown from year to year. A critical review will not be attempted. The great difficulty with most books, from the standpoint of the nonspecialist, is that they are hard to understand, and while the writer is not competent to criticise them further, he feels that they have not been of much value to many who would like to know something of the subject, even though they have no idea of specializing in it. He has for a long time been convinced that the average doctor should know more about mental hygiene, and therefore welcomes a book of this type.

The authors of this book have had experience in practical work as well as in teaching, and it is apparent that they can write understandingly for the educated layman. Such problems as those of childhood, adolescence, marriage, religion, school and college, recreation, etc., are necessarily of interest to everyone in this complex world.

Each chapter ends with suggestions for classroom discussion and written reports, and some illustrative cases are given. There can be little doubt that the average university faculty, medical as well as lay, knows little about mental hygiene, and often cares less, due

to the fact, probably, that it is a new science, and even among physicians is regarded as an abstruse specialty for the few. The authors discuss some methods by which faculties may be interested, and one cannot read this book without becoming convinced that knowledge of the subject which it discusses should be widely disseminated.

Of the many problems which arise in the lives of all, there is scarcely one that is not discussed sanely and helpfully. The great value of the book from the standpoint of the reviewer, apart from its soundness, is that it is understandable, and one does not have to be versed in the language of the alienist to profit by it. The reviews of the book by specialists have been favorable from the professional standpoint. In view of these and his own experience with it, it is recommended to the average reader with confidence. The printing and make-up are excellent.

M. P. RAVENEL

Tuberculosis Among Children—
By J. Arthur Myers. Springfield, Ill.: Charles C. Thomas, 1930. 208 pp. Price, \$3.50.

During the current year an attempt is being made to emphasize the importance of and to spread the knowledge about childhood tuberculosis. It is, for this reason among others, important to call attention to Dr. Myers's book on tuberculosis in children. The book contains little that is new but summarizes well what is known. It is of interest to note that in the diagnosis of tuberculosis in infancy and in childhood two measures only are of much significance, the tuberculin skin test (preferably the intracutaneous) and the roentgenological examination. In prophylaxis the importance of infection from tuberculous infants, children, and adults is stressed but no opinion is ventured upon the advisability of the use of BCG.

In the treatment of tuberculosis at these ages life in the open is less helpful, he thinks, than in a well ventilated room with the temperature and moisture controlled. Dr. Myers attributes to McPhedran the discovery that some of the hilar shadows are not glands but blood vessels seen end-on, while the reviewer has always been under the impression that John Weber of California first called attention to it. It is of interest to note that these little patients can be given too much fresh air. The possibility of a filterable form of the tubercle bacillus and the great value of diet in the treatment of lupus are not mentioned.

The author mentions combining X-ray and heliotherapy in the treatment of cervical adenitis but fails to warn of the danger of an X-ray burn when both are applied over the same area. It is jarring to see the word hemorrhage used as a verb. In another edition it is to be hoped that the quantity of tuberculin will be given in cubic centimeters and not in milligrams.

The book is excellent, typographically pleasing, and it is hoped and predicted that it will have the large circulation that it deserves. LAWRASON BROWN

Report on Methods of Analyzing Butter—Geneva, N. Y.: *New York Agricultural Experiment Station*, 1930. Price, \$.25 each report.

The American Dairy Science Association through its Committees on Chemical and Bacteriological Methods of Analyzing Butter has recently issued a report describing these methods. This appeared in the *Journal of Dairy Science* for September, 1930, published by the association.

The report on the chemical methods of analyzing butter has been prepared under the general supervision of Dr. A. C. Dahlberg by a sub-committee consisting of Professor E. S. Guthrie, Chairman, Professor V. C. Manhart,

Professor D. H. Nelson and Professor H. B. Ellenberger. The chemical section of this report is largely taken up with a discussion of the two general methods of making a complete analysis of butter in creameries. These are the procedures recommended by the Association of Official Agricultural Chemists and the Kohman test. The former method is generally used by federal government and state chemists, but the latter test is simpler of operation and satisfies the practical creameryman better. The entire discussion of methods is from the standpoint of a complete analysis of butter in the laboratory rather than for a rapid churn test and has been drawn up for industrial laboratory men rather than for the official control laboratory.

The microbiological methods have been drawn up under the general supervision of Dr. R. S. Breed by a sub-committee consisting of Professor E. H. Parfitt, Chairman, Dr. E. G. Hood, Professor B. W. Hammer and Professor H. Macy. Like the report on chemical methods this report has been drawn up primarily for industrial laboratory workers, and it gives a series of suggested methods for determining the number and kind of microorganisms in butter rather than an official procedure. Naturally the greater part of the report has been taken up with a discussion of the determination of the number of yeasts and molds in butter. This section is followed by a discussion of methods of determining the total number of bacteria present, the number of protein digesting bacteria present, and microscopical methods of examining butter for microorganisms.

This is the second in a series of reports on methods in analyzing dairy products to be issued by the Dairy Science Association, the ice cream report having been issued in 1927. Reprints of either report are available.

R. S. BREED

The Measurement and Control of Municipal Sanitation. *Committee on Uniform Street Sanitation Records of the International Association of Street Sanitation Officials, Chicago: 923 East 60th Street.*

In an address before the Sanitary Division of the American Society of Civil Engineers last January the reviewer pointed to the unsatisfactory state of development of municipal cleansing service in the United States and showed the impossibility of getting from the large cities figures by which to judge the relative cost of this work. The annual per capita cost among 24 cities answering inquiries ranged from \$.65 to \$4.46, according to the official data. Obviously the reports did not always cover the same items. There was no standard method of reporting or measuring the work done and in many instances it was impossible to get a clear picture of it. This situation could and should be changed.

The International Association of Street Sanitation Officials, made up largely of persons engaged in street cleaning and the collection and disposition of municipal refuse in the United States and Canada, appointed in 1928 a committee to collaborate with the National Committee on Municipal Standards to prepare a report on standards of measurement for this kind of service. The International City Managers' Association also entered with money from the Julius Rosenwald Fund and the University of Chicago, a part of which could be devoted to the committee's work. The report here reviewed is the product of this joint movement, or perhaps more accurately of Donald C. Stone, Gustave A. Moe and Clarence E. Ridley, whose advocacy of modern scientific business methods in municipal administration has attracted much attention.

Despite its title, the report has nothing to do with the measurement and

control of sanitation, except as related to the collection and disposal of municipal waste, snow, and the cleaning of catch basins, and in the field which it does cover, no help is offered on the subject of standards of cleanness or efficiency. These omissions are fully realized by the authors, who say they must be "taken into consideration," but do not tell how this should or can be done. And so with snow removal, the difficulties connected with measuring this work are catalogued, but no measure is proposed. Here is an old question which has puzzled commissions of engineers.

Perhaps no question of municipal administration offers so many difficulties to those who would introduce scientific methods of measurement and cost accounting as street cleaning, refuse collection and disposition, and snow removal.

Of the 3 parts into which the report is divided, (1) the need of measurement standards in municipal sanitation, (2) measurements applied to sanitation activities, and (3) records and cost accounting procedure, the first is the longest. The report is a vigorous argument for the adoption of uniform and suitable methods of measuring and recording the work done in cleaning street pavements and collecting, transporting and disposing of the solid refuse of the streets and houses, and for sound records which mean something. As the authors point out, "Accurate records of work performed and its cost are vital to good budgeting."

The unit proposed for street cleaning is the "curb mile" or the "cleaning of half of the street parallel to each curb line, including intersections, for a distance of one mile." By this is meant the combined lengths of both curbs. This unit does not show how many square yards are cleaned nor how many times the whole surface is gone over. The width of the street is not

taken into consideration. The unit has no relation to the dirtiness, state of repair, or kind of pavement, the season, weather, state of the traffic, or any other of the many conditions which enter into the difficulty and cost of this kind of work, and make it so hard to measure satisfactorily.

The report favors the short ton as the unit of measurement of refuse, but when it cannot actually be weighed, recommends that the volume be estimated.

The document is put forward as a tentative draft, a "skeleton" of what the final report will be. The committee plans to design a guide for sanitation officials in preparing their annual departmental reports. The committee is under no illusions concerning the size and difficulty of the task. It has made a good beginning. Let us hope it will be strong enough to carry out the whole task in a businesslike and practical manner.

GEORGE A. SOPER

Practical Applications of Heredity

—By Paul Popenoe. *Baltimore: Williams & Wilkins, 1930.* Price, \$1.00.

This little book is largely made up of essays which have already appeared in several more or less popular journals. The titles are all interesting. There are many anecdotes of well known geniuses as well as impostors, some of whom have assumed this rôle for profit and some from mental derangement.

The book is charmingly written and contains much practical advice.

M. P. RAVENEL

A Study Guide Text-book in the Principles and Practice of Nursing

—By Lulu K. Wolf. *New York: Macmillan, 1930.* 139 pp. Price, \$70.

This book should prove a valuable aid to the busy instructor who has found the work of making out adequate

sets of the new type questions both puzzling and time consuming. It is particularly good for the student to have the subject material covered by questions which are not in her instructor's own familiar phraseology.

Each set of tests seems especially well planned to impress the student with the necessity for definite clear cut facts rather than the vague impressions which sometimes pass for knowledge. The clever hints at several possibilities in many of the answers where only one may be used are stimulating to any reader (instructor included) to search for exactness in information.

A problem to be worked out by a study of suggested references is skillfully presented at the beginning of each lesson. References are clearly indicated.

There is a strong, splendid appeal in the paragraph which the author calls a "Foreword" following each problem. Instructors and executives who are aware of the difficulties met in placing serious responsibilities on youthful shoulders will find a frequent reading of these well-thought-out paragraphs both stimulating and inspiring.

There are numerous suggested graphs showing means of working out class relationship curves, etc., which some instructors are finding useful for creating a desire in their students for creditable rating.

HARRIET E. DAVIS

Introduction to Human Parasitology

—By Asa C. Chandler, M.S., Ph.D. (4th ed.) *New York: Wiley, 1930.* 655 pp. Price, \$5.00.

This volume, rewritten and enlarged, supersedes the well known text, *Animal Parasites and Human Diseases*, by the same author.

A book which has been so long before the public and has been so favorably received by teachers as well as critics needs no comment further than to say that the new volume has been improved

in practically every way and brought up to date. It is an eminently practical book for the teacher as well as the practitioner.

The illustrations are good and abundant. The printing and binding are excellent. We know of no text on this general subject which can be as unhesitatingly recommended.

M. P. RAVENEL

Is It Safe to Work? A Study of Industrial Accidents—By Edison L. Bowers. *New York: Houghton Mifflin, 1930. 229 pp. Price, \$2.50.*

Why is it that we, who have such a hatred for war, condone a continual battlefield in industry, where the casualties exceed those of war? Reliable authorities agree that 75 per cent or more of all accidents could be avoided. In brief, the book gives clear and practical suggestions for the prevention of accidents and discusses compensation, and the re-training of injured workers, all three of which subjects are insisted upon as related parts of one comprehensive program. The work is by a professor of economics who is also the author of the book *Compulsory Automobile Insurance*.

Gross injustices in our present workmen's compensation system exist, and scientific treatment of the injury problem has been made impossible because of the conditions surrounding the passage and administration of accident, compensation, and vocational rehabilitation legislation. The potential relationships between these three still remain for the most part unappreciated.

Each of the 14 chapters ends with a

concise summary and conclusion, and the subject matter, which is commensurably rich in statistical evidences, takes up the workmen's compensation systems and schedules in the United States and foreign countries with special chapters devoted to the California and British Columbia Systems and another upon the American Rehabilitation System. The present death benefits are considered inadequate, which in itself causes serious problems, for which industry should be held responsible. The American safety movement and the fundamentals of accident prevention, with their relations to compensation laws and merit premium rating, comprise another chapter, while the two final chapters are devoted to "Outlines of a Permanent Partial Disability Schedule" and "Workman's Compensation or Limited Insurance?" Efforts to improve compensation must always have as their ultimate aim injury prevention. Safety is, after all, the real challenge to industry today. New methods and increased production demand that producers be held accountable for safety, and purchasers should pay the cost.

There is a set of notes for each chapter and an unusually replete bibliography classified under General Treatises, Accident Prevention, Workman's Compensation, and Rehabilitation.

The present work is a forcible presentation of the essentials, shortcomings, and possible solutions of the great "accident-compensation-rehabilitation" question. The material is fluently presented, the type is large and readable, and the subdivisions are logically captioned.

EMERY R. HAYHURST

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Measuring Municipal Sanitation
—The Committee on Uniform Street Sanitation Records of the International Association of Street Sanitation Officials has published under date of September, 1930, a tentative draft of a report on the measurement and control of municipal sanitation. City administrators will find much valuable material here.

The need of measurement standards in municipal sanitation, measurements applied to sanitation activities, and records and cost accounting procedures are the major topics treated. In the words of the committee, the purpose of this manual is

(a) To provide the sanitation administrator with the proper information to plan, supervise, and control the operations of his department, (b) to furnish him with a factual basis for preparing budget and appropriation estimates, (c) to supply him with a method of reporting his work to the public, and (d) to develop sufficient uniformity in reporting so that the administrator can compare his quantities, costs, and methods with those of other cities.

Pittsburgh County, Okla.—This very attractive annual report of 13 pages describes the work of the coöperative health unit in 1929 for this county of 1,370 square miles, with 50,778 population. There are 116 schools with an enrollment of 11,000. Disbursements amounted to \$10,000.

There were 136 lectures given with an attendance of 1,311 in addition to 97 group conferences. Photographs illustrate the work being done to improve sanitary conditions. About half of the population have been inoculated with typhoid vaccine. There were 29 cases of typhoid and 24 cases of tuberculosis reported last year. The health department has 23 tuberculosis cases under supervision while 13 are in institutions. Prenatal conferences numbered 43, with

an attendance of 150, while 114 home nursing visits were made to these cases. There were 354 babies examined in conferences and 133 home nursing visits made in behalf of these children. School work included 2,277 physical examinations.

Wood County, W. Va.—This is an interesting and well printed report of a county health department operating on a budget of 24 cents per capita. The milk supply is over 50 per cent pasteurized and is supervised by frequent inspections (350 dairy farms) and laboratory examinations. Nearly half of the 285 laboratory tests showed bacteria counts under 50,000 during the year. There are 20 retail dairy farms and 2 pasteurizing plants.

During the year 523 physical defects were corrected among school children, 700 persons were inoculated with typhoid vaccine, 600 were vaccinated, and 4,200 complete diphtheria toxin-antitoxin administrations were given.

Quincy, Mass.—The 1929 report is modelled, as heretofore, on the *Appraisal Form for City Health Work* of the American Public Health Association. A rating of 742 points compares with 712 in 1928. An organization chart prepares the reader for a clear understanding of the report of community health services.

There were 18 cases of diphtheria reported during the year with 2 deaths. As in previous years, prevention clinics were held weekly in various wards, and 3,700 children, half of whom were of school age, were immunized. In the child hygiene clinics there was a registration of 3,259, with an attendance of 7,154, besides 3,817 home visits by nurses in behalf of these children.

There were 397 visits made by children to the habit clinic with 737 visits to homes by the social worker.

Newton, Mass.—Careful preparation and good printing in readable type on dull coated paper characterize this health department report of 15 pages. A death rate of 9.8, based on a population of 58,758, with a birth rate of 14.9 and an infant mortality rate of 47.8 are statistical records worthy of note. Per capita expenditures amounted to 71 cents.

There were only 7 cases of diphtheria with 1 death. During the past 5 years there have been but 2 deaths from this disease. In each instance, the patient was not brought under treatment until the 3d or 4th day after onset. There were 367 kindergarten children immunized during the year. Approximately 96 per cent of the milk supply of the city is pasteurized.

Hartford, Conn.—On the basis of an estimated population of 176,318, a resident death rate of 10.4 and a birth rate of 17.5 are recorded in the 1929 report of the Board of Health. This city also reports an infant mortality rate of 71.1.

A detailed financial statement, classified by functions, shows total expenditures of \$182,172, of which \$82,520 were for the isolation hospital. Receipts amounted to \$21,299, of which \$16,251 were derived from the hospital. In common with the rest of New England, Hartford experienced a severe epidemic of respiratory disease and influenza in January. There were no deaths from typhoid or scarlet fever during the year. Diphtheria, measles, and whooping cough each yielded a death rate of 2 per 100,000. The death rate for tuberculosis was 77.1, compared with 71.9 in 1928, the 1929 rate among whites being 64.5 and among the colored, 400.

A juvenile tuberculosis clinic has been maintained at the Hartford Dispensary, at which 233 children received Mantoux tests and 174 physical examinations were made. The appraisal score for 1929 was 955 points out of a possible 1,400.

Springfield, Mass.—The birth rate for the year 1929 was 21.5 per 1,000 population, an increase of 1.5 over 1928. The crude death rate was 12.3 per 1,000; the infant mortality rate 54.5 per 1,000 births. The following specific death rates (per 100,000 population) were shown: tuberculosis 52, typhoid fever 0.6, diphtheria 1.5, measles 4.5, whooping cough 1.3, scarlet fever 0.6, heart disease 243, cancer 137.

Medical supervision is given to all the public and parochial schools in the city, except the high schools. The entire school system is provided with nurses, 64,620 school inspections having been made in 1929. Thirty-eight nutrition classes have been formed for children who are at least 8 lb. underweight for height and age. Six dental dispensaries are provided, so that all the school children in the three lower grades are receiving the necessary care and treatment of teeth. Children in the nutrition classes receive the necessary attention regardless of grades.

The per capita appropriation for health in Springfield is \$1.38, as shown in the 1929 annual report. The department hospital receives 63 cents; 33 cents is used for medical inspection of school children.

Los Angeles County—A supplemental annual report of the Board of Supervisors deals with Public Health and Welfare Activities for the year ending June 30, 1929. Administrators will be particularly interested in the photographs and architect's plans of health centers which form an important part of the county health and welfare program.

It is our belief that the efficiency developed by grouping the health department, county welfare, school and other workers in the districts together under one roof has proven to be one of the greatest advances in service to the people performed by the County Government within recent years. We are happy to state that the Grand Jury report of 1928 and the survey conducted by the Bureau of Efficiency, assisted by the American Public Health Association, not only revealed no serious weakness in the department but strongly supported our policies and management.

Functional organization charts include personnel and salaries for each bureau and division of the health department. Extensive statistical tables accompany enlightening descriptive text. In the division of accounts is a business manager. A comprehensive report system is maintained showing the work performed in and costs to the 35 cities with whom contracts are made by the county department. Annual summary sheets are compiled showing the units of service and the costs for the various health districts. The Hollernith Division tabulates 63,000 cards monthly. There are 10 buildings owned by the County with approximately 65,000 square feet of floor space, besides 12 buildings rented with approximately 11,000 square feet, 28 other buildings in which the department is given the free use of 81 rooms, besides 33 rooms occupied in municipally owned buildings.

Functional studies of the city and county health expenditures of public and private agencies are tabulated to show a combined per capita total of \$2.98, \$1.60 by city agencies and \$1.38 by county agencies. The county health department budget for the fiscal year was \$1,092,691, of which \$696,733 was for salaries, \$200,530 for current expenses, \$64,313 for outlay, and \$131,115 for structural expenses.

Medical social service forms an important part of the work and many thousand contacts were made and inter-

views were held with health center cases during the year. Among other services, 2,150 cases were admitted for medical care, while 692 others were referred to physicians and dentists as not being eligible for treatment at the centers according to existing "Standards of Eligibility."

The personnel of the bureau of maternal and child hygiene consists of 39 full-time and 6 part-time trained physicians, dentists and assistants, exclusive of public health nursing supplied by a special bureau. There were 487 prenatal cases who made 2,571 clinic visits, while 52,044 infant and preschool visits were made to medical conferences. The services of this bureau may serve as an illustration of the activities of the health department described in the comprehensive report.

Connecticut—The 10th report of the Connecticut Public Health Council for the year ending June 30, 1929, occupies 476 pages of descriptive text, tables, charts and maps, and includes a full account of the successful New England Health Institute of 1928, when 1,200 were registered, and the Fiftieth Anniversary celebration of the Department. A classified statement of disbursements for the fiscal period July, 1928–June 30, 1929, shows total expenditures of \$281,881.

The second lowest annual death rate of 11.1 is recorded for 1928, the rate for the previous year being 10.6. Typhoid fever (0.6), scarlet fever (1.4), diphtheria (5.3), and diarrhea and enteritis reached record low death rates. An average infant mortality rate of 65.6 for 4 years 1925–1928 contrasts with a rate of 142.8 for the 5 years 1900–1904. The major new activity was the survey of hospitals and their licensing as provided by a law passed in 1927. Fifteen hospitals were licensed for general use and 41 for chronic and convalescent care. The Division of Occupational Diseases has extended its services and

reporting of cases has increased considerably.

A tabular review of the Public Health Instruction Service indicates that during the year there were 280 film showings, 162 public addresses, 4,819 slides used, 35 strip film and 77 lantern showings, 811 posters displayed and 21 exhibits prepared.

The revised directory of nurses shows 3,552 on the list, 355 being engaged in general public health work in the State, 142 in school nursing, 119 in industrial nursing, 788 in institutions, and 1,718 in private duty nursing, among others. Of the 3,552, 713 are inactive or residing out of the State. Field supervision and advice is given by the Bureau of Public Health Nursing.

Well child conferences under state auspices number 58. At these conferences 3 kinds of services are rendered: (1) for very young children, a physical examination and advice to mothers; (2) for children about to enter school, a physical examination and particular advice about correction of defects before school begins; (3) for the 4 to 6 year-old children, the cleaning of the teeth and instruction and demonstration of their care. In certain localities, the dentists give their services, and at each child conference local physicians give their services in examining children. Reports of the various other bureaus and divisions, including laboratories, sanitary engineering, and mental hygiene, indicate an impressive volume of work which is interestingly described by the use of maps, tables and charts accompanying descriptive text.

White Plains, N. Y.—In the Health Conservation Contest of the U. S. Chamber of Commerce in 1929, White Plains was awarded first place among cities of 20,000 to 50,000 population. This 5th published annual report of the department reflects credit to the city and the staff for the health program

which has been developed. In the words of the health officer, "as the years have passed, the ideals of preventive medicine have gradually become an accepted part of our community life." It is noteworthy that the Mayor "has attended all meetings of the Board and his advice has been graciously extended on many occasions."

On the basis of a population of 32,250, a death rate of 9.9, a birth rate of 21.9 and an infant mortality rate of 40 are recorded. The health of 403 infants, 337 preschool children and 166 expectant mothers was supervised in the health department clinics, while 6,479 school children were under the medical supervision of the Department of Education. Fifteen clinics were held in the spring and fall for the immunization of children against diphtheria (417) and vaccination against smallpox (157).

The budget of the health department amounted to \$1.23 per capita. In addition, expenditures of the board of education for the health work amounted to 64 cents per capita, and those of the Nursing Association to 77 cents per capita. The Department of Charities expended \$2.91 per capita for hospitalization and care of communicable disease, tuberculosis, maternity, psychopathic, and other types of cases. On the *Appraisal Form for City Health Work* the public health work of the city scored 812 out of a possible 1,000 points. The report of 71 pages is well illustrated with photographs and charts.

East Orange, N. J.—The new health building is effectively pictured on the cover of the 15th annual report of East Orange for 1929. This new health center was erected by the city as one of the units in its new Civic Center. A reproduction of the award of the U. S. Chamber of Commerce for the best accomplishments in health conservation in cities of 50,000 to 100,000

in 1929 features the first page. This is followed by an appraisal chart of health practices which shows a rating of 880 out of a possible 1,000 points, which compares with a score of 848 in 1928.

"The year gives us the smallest number of scarlet fever cases on record, there being only 73 cases reported. A reduction in the cases of diphtheria from 46 the year previous to 33 for this year, in spite of a high prevalence in neighboring communities, speaks for itself, emphasizing the importance of diphtheria immunization." Preschool immunizations against diphtheria increased from 569 to 706, two-thirds of the increase being accounted for by physicians in private practice.

This city, with a population of 70,888, records a birth rate of 12.7, 80 per cent of the births occurring in hospitals. Population, birth and death rates are analyzed by wards. A death rate of 9.5 is reported. Of special interest to administrators is a report of a prevalence study of venereal diseases which showed a rate of cases under treatment on a given day of 3.8 per 1,000 population, 2.3 for syphilis and 1.5 for gonorrhea. Adjustments based upon the annual turnover of these diseases raises the an-

nual incidence to 8.9, 2.3 for syphilis and 6.6 for gonorrhea.

A tuberculosis death rate of 35 is recorded, as compared with 84 for the years 1915-1919. The tuberculosis control work of the city is carried on by the Anti-tuberculosis League of the Oranges and Maplewood. There were 68 cases reported in 1929, and 229 cases in the active file at the close of 1928. A special study of deaths among females for the years 1920-1929 fails to show the increase at ages 15-25 noted for the country as a whole. Of cases in sanatoriums, 32.4 per cent were in the incipient stage. The total patient days of 71 cases amounted to 13,056, with an average length of stay of 189 days.

An increase in laboratory analyses is noted since the health department moved into new quarters. During the year, 5,614 examinations were made in the city and other local laboratories. This comprehensive report, which is one of the best of the year, concludes with 7 recommendations by the health officer, a report of the finance committee showing an expenditure of \$47,514, and a list of members of the board of health and the staff of the health department.

Panama Canal Zone Health Administration—Not only the well known anti-mosquito work, but the many other successful projects of the Panama Canal Health Department are interestingly recounted.

CHAMBERLAIN, W. P. The Health Department of the Panama Canal. *New Eng. J. Med.*, 203, 14: 669 (Oct. 2), 1930.

Poliomyelitis Virus Studies—Concentrated poliomyelitis virus remains potent more than 4 months. Streptococci were no longer viable after 35 days. This finding tends to discredit the streptococcus as a specific agent of the disease. Attempts to cultivate any organism were negative.

CLARK, P. F., *et al.* Some Properties of Poliomyelitis Virus. *J. Bact.*, 20, 3: 213 (Sept.), 1930.

Influenza-Pneumonia Mortality—A 20-year study of the deaths from influenza and pneumonia is presented in the form of graphs for each of 50 cities.

COLLINS, S. D., *et al.* Mortality from Influenza and Pneumonia in 50 Large Cities of the United States, 1910-1929. *Pub. Health Rep.*, 45, 39: 2277 (Sept. 26), 1930.

Typhoid Vaccine After Infection—Persons who received prophylactic injections of typhoid vaccine after infec-

tion but before symptoms commenced had an attack of much shorter duration and milder symptoms than those who received no vaccine.

CROUCH, J. H. A Study of the Effect of Typhoid Vaccine When Given After Infection. *Pub. Health Rep.*, 45, 41: 2429 (Oct. 10), 1930.

Training of Health Workers in Great Britain—This interesting symposium on the training of medical officers of health, practicing physicians, health nurses and sanitary inspectors will prove of value to American educators who are training the sanitarians of the future.

FITZGERALD, J. G., *et al.* General Outline of the Problem of Training Health Workers. *Brit. M. J.*, 3641: 631 (Oct. 18), 1930.

Health Education vs. Health Ignorance—As forceful as it is modest is this answer to the recent utterances of a visiting British medical celebrity and the president of our own medical association, to wit, that in the realms of health, ignorance is truly blissful.

FRANKEL, L. K. The Future of Medical Practice. *New Eng. J. Med.*, 203, 15: 713 (Oct. 9), 1930.

Breast vs. Bottle Feeding—Poor economic and hygienic conditions, rather than breast or bottle feeding, are responsible for frequency of infection and instance of infant mortality. In districts where economic and hygienic conditions are good, the average bottle-fed infant does as well as the average breast-fed baby. Uncomfortable findings for the breast feeding propagandist.

GLAZIER, M. M. Comparing the Breast-Fed and the Bottle-Fed Infant. *New Eng. J. Med.*, 203, 13: 626 (Sept. 25), 1930.

Undulant Fever—Young adults, especially men on farms or in packing houses, are most frequently the victims of undulant fever, a widespread disease caused as often by contact with infected animals, or their tissues, as by drinking unpasteurized milk from diseased cows. An authoritative and exhaustive study.

HARDY, A. V., *et al.* Undulant Fever. Pub. Health Rep., 45, 41: 2433 (Oct. 10), 1930.

Rural Health Administration—The annual progress report of the rural health work in which the U. S. Public Health Service coöperates evidences again the irresistible trend of this most important activity.

LUMSDEN, L. L. Coöperative Rural Health Work of the Public Health Service in the Fiscal Year 1930. Pub. Health Rep., 45, 43: 2613 (Oct. 24), 1930.

Industrial Nursing—Excellent advice for the industrial nurse presented effectively.

McCONNELL, W. J. Practical Suggestions for Nurses in Industry. Pub. Health Nurse, 22, 10: 509 (Oct.), 1930.

Training Health Officers—Describing the coöperative project of the Tennessee State Department of Health and Vanderbilt University in which health officer candidates undergo class room and field training.

MOUNTIN, J. W. The Training of Health Officers. Pub. Health Rep., 45, 40: 2378 (Oct. 3), 1930.

Early Detection of Tuberculosis—A plea for a program of early detection of tuberculosis in children, so that by suitable treatment clinical disease in adults may be prevented.

ORIE, E. L. The Significance of Advanced Tuberculous Infection of School Children. J. A. M. A., 95, 16: 1151 (Oct. 18), 1930.

Prophylactic Vaccination Against Colds—Catarrhal vaccine seems to be helpful as a prophylactic in half the persons who take it.

MURRAY, H. G. Prevention of Colds by Vaccine Therapy. New Eng. J. Med., 203, 15: 727 (Oct. 9), 1930.

Dairy Farm Inspection—An interesting account of the District of Columbia dairy inspection service well fortified with convincing photographs.

SANDS, E. R. Inspection of Dairy Farms. Munic. San., 1, 10: 557 (Oct.), 1930.

Home Care of Cardiacs—Types of cardiac cases among children are classified and the nursing care of each class is considered.

SUTTON, L. P. Follow-up Care of Cardiac Children in the Home. Pub. Health Nurse, 22, 10: 503 (Oct.), 1930.

Vitamins in Cereal—A new breakfast cereal rich in vitamins and minerals is suggested. It is composed of wheat, oat and corn meal, wheat germ, bone meal, brewer's yeast and alfalfa. It is palatable.

TISDALL, F. F., *et al.* A New Cereal Mixture Containing Vitamins and Mineral Elements. Am. J. Dis. Child., 40, 4: 791 (Oct.), 1930.

School Child Health Administration—An inclusive discussion of sanitary, medical, and hygienic (personal) aspects of school health.

WILSON, C. C. School Health Education. J. Health & Phys. Ed., 1, 8: 12 (Oct.), 1930.

Water Treatment—A progress report covering modern methods of filtration, chlorination, taste and odor removal and laboratory control.

WOLMAN, A., *et al.* Recent Progress in the Art of Water Treatment. J. Am. Water Works A., 22, 9: 1161 (Sept.), 1930.

NEWS FROM THE FIELD

NATIONAL COMMITTEE FOR MENTAL HYGIENE OFFERS FELLOWSHIPS

TO assist in lessening some of the shortage of properly trained psychiatrists The National Committee for Mental Hygiene offers fellowships toward the acquisition of the special preparation required. Details of these fellowships can be had from Dr. Frankwood E. Williams, Medical Director, National Committee for Mental Hygiene, 370 Seventh Avenue, New York, N. Y.

INTERNATIONAL ASSOCIATION OF MILK DEALERS CONVENTION

THE International Association of Milk Dealers held its twenty-third annual convention at the Hotel Statler, Cleveland, O., October 20, 21 and 22.

The election of officers at the close of the convention returned Dr. F. D. Walmsley to the presidency of the association for another year. L. A. Van Bomel, president of Sheffield Farms Co., New York, N. Y., was reelected vice-president; Dr. D. B. Peck of the Bowman Dairy Co., Chicago, Ill., was named treasurer again; and R. E. Little, of Chicago, was reelected executive secretary.

NEW YORK SOCIETY FOR THE EXPERIMENTAL STUDY OF EDUCATION

THE Health Education Section of the New York Society for the Experimental Study of Education held its second dinner meeting at the Men's Faculty Club of Columbia University, New York, N. Y., November 14, 1930.

Dr. Percival M. Symonds, Chairman of the Mental Hygiene Committee of the White House Conference, addressed the group on needed research in Health Education.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS

THE International Association for the Prevention of Blindness held its annual meeting on Friday, October 10, at the Palais des Academies, Brussels, Belgium. Numerous ophthalmologists attended this meeting, and interesting national reports were made, dealing with the prevention of those diseases and accidents which lead to destruction or impairment of sight.

MISSOURI WATER AND SEWAGE CONFERENCE

THE Sixth Annual Meeting of the Missouri Water and Sewerage Conference was held in Columbia, Mo., October 23-24-25, 1930. The following officers were elected for the coming year: Chairman, J. N. Wells, Joplin; Vice-Chairman, E. E. Wolfe, Hannibal; and Secretary-Treasurer, H. D. Peters, Jefferson City. Executive Committee: R. L. Barker, Odessa; O. L. Hebbler, Higginsville; Hugh Brown, Vandalia, and W. J. Gray, Springfield.

AMERICAN JOURNAL OF CLINICAL PATHOLOGY

DR. T. B. Magath of the Mayo Clinic has accepted appointment as editor-in-chief of the new official journal of the American Society of Clinical Pathologists, the *American Journal of Clinical Pathology*, of which the first number will be issued in January 1931.

The new journal will emphasize new methods in laboratory work, the material being primarily of a practical and clinical nature. It is designed to be useful and serviceable to the technician as well as to the pathologist. For the present the journal will be published bimonthly.

DELTA OMEGA NEW OFFICERS

JOHN A. Ferrell, M.D., of the Rockefeller Foundation, New York, N. Y., was elected president of Delta Omega, the honorary public health society, at the annual meeting held in Fort Worth, Tex., October 29, 1930. Dr. Ferrell succeeds C. C. Young, D.P.H., of Lansing, Mich. Other officers elected were James A. Tobey, Dr.P.H., New York, as vice-president; and Professor Ira V. Hiscock of the Yale School of Medicine as secretary-treasurer. George W. McCoy, M.D., Director of the National Institute of Health, Washington, D. C., was elected an honorary member of the society.

Delta Omega now has 316 members, distributed in 6 chapters at the Johns Hopkins School of Hygiene and Public Health, Harvard School of Public Health, Massachusetts Institute of Technology, University of Michigan, Yale School of Medicine, and University of California. The honorary members of the society include President Hoover, Surgeon General H. S. Cumming, Charles V. Chapin, M.D., F. F. Russell, M.D., Sir Arthur Newsholme, W. S. Rankin, M.D., and S. Josephine Baker, M.D.

The society has made arrangements with the American Public Health Association for the reprinting of Dr. William Budd's classic work on typhoid fever, which first appeared in 1873.

NEGRO PUBLIC HEALTH NURSING

THAT the most urgent needs of the Negro public health nursing group are better fundamental training for the Negro nurse herself and a willingness on the part of whites to accord professional standing to her, are the chief findings of a preliminary survey of public health nursing by and for Negroes conducted under the auspices of the Julius Rosenwald Fund. Data for the survey were gathered by Marjorie Stim-

son, assistant director, and Louise Tattershall, statistician, of the National Organization for Public Health Nursing. A compilation by Stanley Rayfield is published in the current issue of *The Public Health Nurse*.

SWEDEN TO GET NEW DENTAL CLINIC

THE City of Stockholm, Sweden, has been offered \$1,000,000 by George Eastman for the construction and equipping of a dental dispensary similar to the Rochester Dental Dispensary, according to announcement made by Dr. Harvey J. Burkhardt, director of the Rochester Dental Dispensary.

GOVERNMENT HOSPITALS IN NEED OF
MEDICAL OFFICERS, NURSES, AND
SOCIAL WORKERS

A GOVERNMENT release states that government hospitals throughout the country, including those under the Veterans' Bureau, the Public Health Service, the Indian Service, and other branches, are in need of medical officers and nurses of various grades, and that Veterans' Bureau hospitals have vacancies in positions of psychiatric social worker and junior social worker.

CHILD LABOR DAY

CHILD Labor Day, the last Sunday in January, presents the opportunity for the people of any state to give thought once again to the conditions of child employment in their own community.

Any one interested in knowing more about child labor conditions can secure information from the National Child Labor Committee, 215 Fourth Avenue, New York, N. Y.

This Committee will send free of charge, to any interested reader, information with regard to child labor in any state together with literature, posters, plays and photographs.

A. N. A. BIRTHDAY

NEXT autumn, the American Nurses' Association will pass its thirty-fifth birthday anniversary. It is making extensive plans now for the observance of this milestone. A membership drive is planned, to commence in early January and to be concluded on the anniversary day, September 2, 1931. The January issue of the *American Journal of Nursing* will carry full plans for this campaign and there will be also a feature story telling of the growth of the A. N. A. from a little group of a score of women to a national organization with 86,000 members.

INTERNATIONAL ASSOCIATION OF DAIRY
AND MILK INSPECTORS

THE 19th annual convention of the International Association of Dairy and Milk Inspectors was held in Cleveland, O., October 23, 24 and 25.

Officers elected for the ensuing year were: President, Dr. A. R. B. Richmond, Toronto, Ont.; First Vice-President, William B. Palmer, Orange, N. J.; Second Vice-President, Dr. Horatio N. Parker, Jacksonville, Fla.; Third Vice-President, Paul F. Krueger, Chicago, Ill.; Secretary-Treasurer, Dr. Paul B. Brooks, Albany, N. Y.

PREVENTION OF BLINDNESS
CONFERENCE

THE 1930 annual conference of the National Society for the Prevention of Blindness was held at the Russell Sage Foundation Building, New York, N. Y., November 17-18. Special sessions included such topics as conservation of vision in school children, the relation of lighting to vision conservation, sight-saving class activi-

ties in America and medical social service in conservation of vision. A feature of this year's conference was the showing of a new two reel motion picture depicting some of the principal causes of blindness and explaining how they may be prevented. Announcement was made of the publication of the new *Sight-Saving Review*, Volume I, Number 1 of which will appear early in 1931.

A NEW METHOD OF MILK PRODUCTION

A NEW system of milk production, eliminating the human factor, was inaugurated at the Walker-Gordon Farm at Plainsboro, N. J., on November 13, 1930, when Thomas A. Edison pressed a button putting in operation a device known as a "rotolactor." This machine comprises a revolving platform with stanchions for 50 cows. As each cow takes her place on the platform, she is washed, dried, a little foremilk is taken for inspection, and then she is milked by machine. At the end of the revolution of the platform, which requires 12½ minutes, one cow steps off, and her place is taken by another. The milk is automatically transferred to a weighing machine, then conveyed through sterile pipes to the filling room, where it is bottled and capped by machine. The milking machines are rinsed and sterilized after each milking.

At the dedication of this new system, Governor Morgan Larson of New Jersey presided, and addresses were made by Secretary of Agriculture Arthur M. Hyde, Dr. Theobald Smith, Dr. Samuel J. Crumbine, and Henry W. Jeffers, president of Walker-Gordon Laboratories, who originated the rotolactor. About 4,000 persons, including many health officials and physicians, attended the ceremonies.

RECENT CHILD-WELFARE MEASURES IN ITALY

THE appropriation for the National Children's Bureau of Italy for the fiscal year, 1930-1931, has been raised to 65 million lire (\$3,399,500), an increase of 35 million over the preceding year. The bureau is engaged in various phases of theoretical and practical child welfare work and maintains many child welfare institutions.—*La Medicina del Lavoro*, N. 2, 1930, p. 75.

NEW PSYCHIATRIC INSTITUTE

THE new Psychiatric Institute of the Grasslands Hospital at Valhalla, N. Y., will open in the near future. The building has a capacity of 82 beds and is modernly equipped.

TUMOR CLINIC

THE Jewish Hospital of Philadelphia will establish a research tumor clinic under the direction of Dr. Leon Solis-Cohen. The clinic will have for its object, not only the treatment of patients according to the best methods of the day, whether medical, radiological, electrical, surgical, or ether, but also and especially the study of the means of early recognition of the affection.

Dr. Joseph C. Doane, Medical Director of the hospital, will act as consulting physician, and on the advisory board. In addition, the members of the visiting staff of the Jewish Hospital will give their services as consultants in medicine, surgery, and the various specialties.

TRAINING OF FACTORY WELFARE WORKERS IN ITALY

A COURSE for the training of women to do welfare work in factories will be started on January 15, 1931, at the School of Social Work in Rome. The curriculum will include certain phases of law, economics, medicine, and hygiene, and methods of social service. The course will last one year.

—*Le Assicurazioni Sociali*, Rome, 4: 186, 1930.

CHILD WELFARE WORK IN THE CITY OF GRAZ, AUSTRIA

THE organization of public child welfare work in the city of Graz is considered as one of the best outside of the capital. The central public authority for child welfare work is the municipal children's bureau, which has 21 branches throughout the city. The bureau has charge of all phases of child welfare work except education. Perhaps the most important part of this work is the guardianship of illegitimate children and legal aid to their mothers, particularly when it is necessary to obtain support from the child's father. Another branch of the bureau's work is the administration of poor relief in the cases of children and young persons under 18 years of age, including the serving of dinners.

At the health centers for expectant mothers maintained by the bureau, the women receive, in addition to medical advice, also gifts of money and clothing.

The bureau is also exercising supervision over wayward children through a staff of trained visitors, and it maintains institutions for such children; it is carrying out the probation work for the juvenile court and is in other ways co-operating with the court.

The municipal centers for children and young persons are also under the direction of the children's bureau; this includes the dental and orthopedic clinics, and clinics for the diseases of the ear, nose, and throat.

The bureau also maintains sanatoriums for tuberculous children and vacation homes for undernourished children, also a health center for expectant mothers, and coöperates with the six infant health centers existing in the city of Graz.—*Ztsch. f. Kinderschutz, Familien- und Berufsfürsorge*, Vienna, 8-9: 118, 1930.

nic described in attempting to confirm or deny results obtained.

These authors took advantage of the opportunity to insist again on the necessity for using naturally susceptible individuals in studies on infectiousness of a given organism and in immunity studies. They further point out a very marked difference between cholera vibrios freshly isolated from the host and organisms that have been long under artificial cultivation. In therapeutic work the use of bacteriophage reduced the mortality from 62.9 per cent to 8.1 per cent. The chapters on epidemiology and on general and specific prophylaxis are particularly interesting from the standpoint of public health.

The most obvious conclusion that can be drawn from this work is that it should be confirmed. There has already been an effort to repeat this work although on a much smaller scale and in another country. The results have been entirely contradictory. It should be mentioned that this work was undertaken by a member of the Pasteur Institute, and it is well known that many of the outstanding members of the staff of this institute are violently opposed to d'Herelle and his work. It is, of course, impossible to state which of the two results are acceptable. The significance of this work is sufficiently great to warrant its further investigation by someone familiar with the technic of bacteriophage but not allied definitely with the supporters of d'Herelle or his active opponents.

N. W. LARKUM

Sanitation, Hygiene, Bacteriology and Sterilization—*By Herman Goodman, B.S., M.D. New York: Medical Lay Press, 1929. 191 pp. Price, \$3.50.*

This little book is one of the Cosmetic Handbook Series intended for the instruction of those known as "cosmetologists."

The author makes a plea for clean

shops which we can endorse. The title shows that the author has attempted to cover a wide field. While we do not, in general, approve of books which give only a smattering of a subject, it must be admitted that the present one is correct as far as it goes, and, for the class of readers for whom it is intended, gives a considerable amount of very useful advice, which, if followed, will improve the profession.

M. P. RAVENEL

An Index to the Chemical Action of Microorganisms on the Non-Nitrogenous Organic Compounds—*By Ellis I. Fulmer, Ph.D., and C. H. Werkman, Ph.D. Springfield, Ill.: Charles C. Thomas, 1930. Price, \$4.50.*

The tables which form the contents of this book will be welcomed by those who are interested in the chemical changes produced by the activity of a great variety of microorganisms in non-nitrogenous substances.

Table 1 enables the reader to gain knowledge as to the general chemical action of a given organism. Table 2 is arranged so as to give information of the various products elaborated from a given substrate by the organism involved. Table 3 lists the types of substrates from which a given chemical has been reported as produced by the named organism.

A list of references is given which is more representative of the recent work. A few errors have crept in: Bio-chem. Z. 174 as of 1906, instead of 1926; Tuikow, instead of Tiukow; Iwatsuru, Rynzo instead of Ryuzo.

The arrangement of the tables is excellent. Their spacing will permit supplementing the given data by personal notes. The authors have purposely limited their material, emphasizing the data concerning the less common types of fermentation, but have included typical references to the common types.

ESTHER W. STEARN

History of Nursing and Sociology—
Compiled by A Sister of Charity of
Emmitsburg, Md. Bridgeport:
Brewer-Colgan Co., 1929. 279 pp.
 Price, \$3.00.

This book could be called "A History of Catholic Nursing and Sociology," and if we accept the author's statement, that the extent of the service of the Catholic Church as a health agency in the United States ranks it in the first place among health forces not supported by public tax, we need to see public health and nursing more through Catholic eyes.

The author has tried to present briefly the important points in the history of nursing which every student nurse and graduate nurse should know. She goes back to the beginning of the history of medicine, shows the influence Christianity had on medical development, and then traces the history of hospitals, before she comes to the origin of nursing.

It is interesting to learn that there are about 30 Catholic orders doing nursing. The Sisters of Charity alone have 200 hospitals. There are in the United States nearly 400 Catholic schools of nursing which are fully accredited.

There are chapters on Organized Catholic Charities, and World War Contributions of American Catholics, though it is a bit difficult to see where nursing ties up with some of the material given here.

There is a long chapter on organizations affiliated with nursing and the contributions they are making to it. The author fails to show clearly how nursing ties up with the National Tuberculosis Association and the American Social Hygiene Association.

The second part of the book deals with sociology from a Catholic point of view and was contributed by Frederick J. Russel, C.M., S.T.D. Here the four chapters deal with Sociology, Hypnotism, Evolution, and Spiritism.

The material in the whole book ap-

pears to be put together in the form of a memorandum, and since there is little order in the arrangement, the lack of an index is perhaps a serious fault, though the author doubtless felt a full table of contents would serve as well. The paragraphs in the first part are brief and concise, but later on there is rather a tiresome amount of detail given in the descriptions of the organizations. There are frequent repetitions, and a great many typographical errors.

There is some new material here but not enough to draw the majority of nurses away from one or two other well known histories of nursing which contain all that nurses need to know of this subject in a much more readable form.

EVA F. MACDOUGALL

The Social Worker in Family, Medical, and Psychiatric Social Work
—By Louise C. Odencrantz. New
York: Harper, 1929. 374 pp. Price,
\$2.50.

Modern social work practices, methods and technics are described in this book in a manner to make it particularly valuable to executives and to those interested in the comparative study and analysis of professional standards. The American Association of Social Workers presents a job analysis study of positions in three fields to which the case work method is common—family, medical, and psychiatric social work.

The first medical social worker began her duties in a hospital in 1905. Present estimates give the number of hospitals and clinics in the United States which have social service departments at about 500, and these include over 1,500 workers.

To make the doctor's work worth while to himself and to the patient, it must be done (in hospitals) in coöperation with someone who has time and ability to teach hygiene and to see that it is carried out, to study the home conditions and report upon their part in causing or prolonging disease, and to help modify those conditions, financial, mental, moral,

which stand between the patient and recovery. This "someone" is the social worker—a man or woman trained to think of a human being as a whole just as naturally as the physician concentrates attention upon a part—(Cabot).

There are some 400 psychiatric social workers in the United States. The psychiatric social worker is defined as a social case worker who has had systematic instruction in the psychological factors underlying behavior and in the principles of physical and mental disease and their social aspects, and training in dealing with psychiatric cases.

In gathering the material for this book, the author consulted executives, supervisors, and staff members, workers "on the job," case records, annual reports, and studies. Public health as well as social workers and hospital administrators will find this an authentic source of valuable information regarding a relatively new profession.

IRA V. HISCOCK

Symposium on Physical Education and Health—Compiled and edited by Jay B. Nash, Emma R. Frazier, and Marguerite Vollmer. New York: New York University Press, 1930. 320 pp. Price, \$2.00.

This publication assembles the papers presented in connection with the dedication of the new building for education in the School of Education, New York University, by 29 contributors.

The book is ". . . dedicated to Clark W. Hetherington whose philosophy has been the inspiration for many of these articles." This is a merited recognition of the fundamental service that Hetherington has given in the organization and development of physical education in New York University. It does not diminish in the least the high value of these papers to call attention to the fact

that their record of Hetherington's contributions to modern thought in physical education is immensely greater than the quotation marks in this symposium indicate. His influence on the science and philosophy of physical education is, and for some years has been, greater than that of any other student in the field of education. His students and auditors have spread his progressive views universally so that they are now largely common property, stressed by authors and teachers, but unrecognized as products of his mind.

THOMAS A. STOREY

Insomnia. How to Combat It—By Joseph Collins, M.D. New York: Appleton, 1930. 131 pp. Price, \$1.50.

Apparently as an interlude in his literary musings on more ponderous subjects, the doctor who has looked at love and life, at literature, and at nearly everything else that editors want, has produced a slim volume on sleep and its cultivation. In it he reveals most of the medical recipes for the treatment and cure of insomnia, with some cursory discussion of dreams, drugs, and diet.

The book is written in an interesting manner, even if it is padded and somewhat repetitious, and the information is eminently practical, even if the customary emphasis is placed on cure rather than on the prevention of the underlying causes of the defects discussed. Thus, much is said about indigestion in relation to insomnia, and something is said about the quantity of food consumed, but there is practically nothing about the quality of nutrition, which is one of the really essential factors in physical welfare. There is an interesting chapter on reading as a soporific. Perusal of this book ought to be quite conducive to sleep. JAMES A. TOBEY

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Milwaukee, Wis.—In the *Bulletin* of the Milwaukee Health Department for February, 1930, is found an excellent summary of the city's health during 1929. Conditions on the whole were satisfactory, notwithstanding the largest influenza epidemic since 1918, and a measles epidemic. The general death rate was 10.5 compared with 10.9 for 1928. The infant mortality rate was 72 per 1,000 births, a slight increase over previous years, partly due to increased hospital facilities which draw ill babies from outlying districts. There occurred 13,198 cases of measles, from which there were only 25 deaths, a fact which indicates that Milwaukee mothers are taking measles more seriously and are providing better medical care. The typhoid and diphtheria rates were the lowest ever recorded, only 25 deaths occurring from diphtheria and 2 from typhoid fever, one of which was a non-resident.

Saskatchewan, Can.—The estimated population of the Province of Saskatchewan for 1928 was 851,000, of which 17.9 per cent resided in towns of 1,000 and over.

The 19th annual health report includes the Vital Statistics Report and is composed of 150 pages, 94 tables, and 26 diagrams, giving detailed information concerning every phase of the department's work. The report shows a total expenditure for health activities of \$794,967 during the fiscal year 1928-1929, which is an increase of \$108,331 over 1927-1928. Of the per capita expenditure of 94.4 cents, 62.1 cents were used as aid to hospitals and sanatoriums, 10.5 for child welfare, hospital management, sanitation, and disease prevention, and 3.6 for school health supervision. Regulations and legislation passed during the year include the

medical examination of employees in hotels and other places, and provision for the formation of "Full-Time Health Districts."

On May 1, the School Hygiene Bureau of the Department of Education was transferred to the Department of Public Health, for which a new branch was created, the Division of Public Health Nursing. A nurse is in charge of each district, which comprises about 6 municipalities. Both school and home visiting is planned, thus including both school and preschool groups. Prenatal work is possible, and material aid is often given in procuring the government maternity grant. In 1928, 1,025 schools were visited and 31,737 children inspected; in 93 preschool clinics 3,546 children were examined, and 9,222 homes were visited.

During the year, 6 new hospitals were added to the list of those receiving government aid. The Province had, in 1928, 3.9 hospital beds per 1,000 population, or 1 bed for every 253.8 persons. Seven per cent of the population had hospital treatment, each patient remaining for an average of 12.3 days. Of the total births, 26.7 per cent took place in a government aided hospital. The report deals in detail with the hospital situation, tables being given which present for each hospital the bed capacities, nursing data, costs and expenditures.

Mississippi Flood Disaster—The American National Red Cross has published a highly interesting and enlightening report of 152 pages on the Mississippi Valley Flood Disaster of 1927. This official record of the greatest relief operations in the history of the organization, and of the administration of the large fund of 17 million dollars, should prove of interest not only to those directly affected by the floods, but

to all who aided in the work or contributed to the relief fund. The report is dedicated to the men, women and children whose sympathy and generosity made possible the relief of 637,000 persons suffering in this great disaster.

The report contains 7 chapters and 12 appendixes, including an excellent bibliography, besides 31 illustrations, charts and maps. The chapters deal with The Flood, Relief Fund Campaign, Organizing Relief Forces, Emergency Period, Reconstruction, Medical and Nursing Service, Financial Control and Audit. Medical and Public Health Measures are described in detail and include an excellent account of the work of nurses. One of the results of the flood was the establishment of full-time county health units in 85 of the flooded counties. The Rockefeller Foundation, in coöperation with the Mississippi Board of Health, also established a training station at Indianola where physicians, nurses and sanitary officers were trained in the practical procedures of public health work. There were 235 health workers, including 85 physicians, 84 nurses and 92 sanitary officers, in training at this center for an average period of 1 month.

Macon City and Bibb County, Ga.—The sixth annual report of the Joint Board of Health for the City of Macon and the County of Bibb, Ga., consists of 48 pages, well printed and bound in light blue covers. The estimated population of the county, including city, was 83,765, of which 46,124 were white persons. A death rate of 12.3 for the white and of 16.6 for the colored population is recorded. Infant mortality has been reduced from 156.6 in 1923 to 68.4 in 1929, while the tuberculosis death rate has declined from 152.6 in 1923 to 89.8 in 1929.

Pellagra cases last year showed a marked increase over the previous year. The department has for several years

kept a supply of yeast for distribution to pellagra cases, and the deaths have decreased. Among the health officer's recommendations are noted the desirability for an increased sewage disposal system (1,266 houses not now being connected in the city of 63,475 population); provision of an incinerator; a contagious disease ward at the Macon Hospital; and provision for hospital care of advanced cases of tuberculosis.

There were 104 prenatal clinic sessions with an attendance of 1,669. There were 52 well baby conferences with an attendance of 535. There were 18,145 children examined by physicians. The laboratory reports 7,566 specimens examined. Expenditures for the year amounted to \$48,315.

Brookline, Mass.—The 1928 report shows an appropriation of \$258,355 and a recommended budget of \$252,731 for 1929, including a hospital relief fund of \$5,109.67 for indigents. A substantial amount has been asked for preventive work, especially the diphtheria vaccination clinic, the health center clinics, the dental and medical inspection of schools, and the school in bodily mechanics. Deaths from cancer show a 30 per cent increase, and pneumonia shows an increase from 25 deaths in 1927 to 44 in 1928.

It is exceedingly difficult for Brookline to compute its birth and death rates on account of the hospitals taking in so many outside patients, and natives of Brookline tend to go away for treatment. The death rate was 11.55, but corrected for residents it was 10.75. In 1927, 70 per cent of the births occurred outside of Brookline. The births and infant mortality rates include only infants of Brookline mothers and exclude births and infant deaths of non-residents. The live birth rate was 11.8 and the infant mortality rate 51.7.

At the health center, 76 preschool children were immunized. The 91 tu-

berculosis clinics made 590 examinations of 277 individuals, of which 106 were new. Twenty-one hundred and thirty home visits were made by nurses.

Lowndes County, Ga.—A good example of what may be done in preparing an attractive and complete report at a moderate expense is that by the Board of Health for 1929. The 16 mimeographed pages give a concise and carefully planned summary of the work for the year, still leaving room for a pleasing title page and artistic division headings.

The staff of the board of health consists of a commissioner, visiting nurse, technician, and secretary. The visiting nurse has under supervision in the county 65 colored midwives. They are organized into 3 clubs at the monthly meetings, at which the health officer or nurse is present. More than 50 per cent of the births in the county are attended by the midwives, nearly all of whom are visited and given instructions by the nurse. The infant mortality rate in 1929 was 42.2 per 1,000 births. A medical inspection was given to all school children in the county, totaling 2,558, of which 1,016 were found to have defects.

The general death rate was 11.7 per 1,000 as compared with 13.4 for 1928. Typhoid fever has declined from 45 cases in 1927 to 8 in 1929. A slight increase in diphtheria cases was noted, as well as in cases of scarlet fever, malaria, influenza and pellagra.

Glendale, Calif.—The annual report of the City Manager for the year 1928–1929 covers 100 pages, illustrated with maps, charts and statistical tables, accompanied by interesting descriptive text. The administration program of the year was carried out with a tax rate of \$1.26 per \$100 on the assessed valuation of taxable property. At the close of the year the City Council decreased

the tax levy to \$1.21. It is noteworthy that operation of the general government has been carried out during the last seven years without a deficit.

Joint arrangement between the city and county was made for the conduct of the health department. This added to the facilities and service afforded and reduced costs. Agreement entered into with the county health authorities calls for the erection and equipment of a health center building by the county on a site to be supplied by the city. Clinics held in the health department include those dealing with cases involving general medicine, surgery, eye, ear, nose and throat, gynecology, pediatrics, health education, orthopedics, physiotherapy, chest, dental service, and child welfare, and prenatal conferences.

The general health record of the city is good.

Dayton, O.—An infant mortality rate of 63 for 1929, as compared with a rate of 66 in 1928, and a general death rate of 11.6 are recorded in the annual report of the health department, published in the January, 1930, *Monthly Bulletin*. "The hub of the health wheel is the laboratory." There were 27,424 examinations last year. In the food inspection bureau, stress is placed upon such matters as healthy food handlers, wholesome food products and sterilization of utensils. In 1929, 17,955 utensils were collected from food establishments for laboratory tests and 13,465 food handler cards were issued after physical examinations were made.

The public health nurses made 62,720 home visits including 911 in homes of preschool children to urge physical examinations in the Summer Round-up. "The Summer Round-up of preschool children is proving an important factor in educating parents in the responsibility of health supervision of their children." All certified milk in Dayton is also pasteurized.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH. D.

Reporting on BCG—This preliminary statement of the effect of vaccinating children exposed to tuberculosis is eloquent of the care being taken to make the study scientifically significant.

ANON. Present Status of BCG Vaccination Against Tuberculosis. *Weekly Bull.* (New York City Dept. of Health), 19, 22: 173 (May 31), 1930.

The Children's Hour—The Health Commissioner of New York City proposes that physicians designate an hour at which they will examine well children and give advice to mothers. The physicians are urged to set a fee and permit their names to be listed. An eminently sensible scheme.

ANON. Preventive Medicine and Private Physicians. *Weekly Bull.* (New York City Dept. of Health), 19, 24: 189 (June 14), 1930.

Immunity to Poliomyelitis—Tests are reported which indicate a widespread immunity to poliomyelitis among individuals not known to have had the disease. This immunity originates in exposure, the virus being spread by person-to-person contact. A very convincing demonstration.

AYCOCK, A. L., and KRAMER, S. D. Immunity to Poliomyelitis in Normal Individuals in Urban and Rural Communities as Indicated by the Neutralization Test. *J. Prev. Med.*, 4, 3: 189 (May), 1930.

Uterine Cancer—The part played by interference with labor in the production of uterine cancer is convincingly portrayed, and the obvious preventive measures are ably discussed.

BLAND, P. B. Remarks on the Prevention of Uterine Cancer. *New Eng. J. Med.*, 202, 25: 1195 (June 19), 1930.

Occupational Mortality—A special analysis of an important investigation

into occupational mortality, presenting some of the findings from the point of view of the industrial hygienist, will be found interesting by all sanitarians.

BRITTEN, R. H. Occupational Mortality as Indicated in Life Insurance Records for the Years 1915-1926. *Pub. Health Rep.*, 45, 22: 1250 (May 30), 1930.

Syphilis Incidence Among Negroes—Blood Wassermanns performed upon a large and unselected group of rural negroes over 9 years indicate an incidence of 19.3 per cent of all males and 18 per cent of all females.

CARLEY, P. S., and WENGER, O. C. The Prevalence of Syphilis in Apparently Healthy Negroes in Mississippi. *J. A. M. A.*, 94, 23: 1826 (June 7), 1930.

Anti-tuberculosis Program—The future program differs from the present in intensity rather than kind, and we must continue to build more solidly on the same foundations upon which we have built for the past quarter century. So concludes the Managing Director of the N. T. A.

EMERSON, K. Where Are We Going in Tuberculosis Control? *New Eng. J. Med.*, 202, 22: 1039 (May 29), 1930.

Mississippi Milk—The adoption of a standard milk ordinance in Mississippi has given three-quarters of the state's urban population milk of high sanitary quality and increased milk consumption.

FUCHS, A. W., and KROEZE, H. A. Results of the Operation of the Standard Milk Ordinance in Mississippi. *Pub. Health Rep.*, 45, 25: 1412 (June 20), 1930.

Viosterol and Rickets—Doubters have arisen to question the rickets preventive potency of viosterol. The research reported here indicates that the recommended dosage should be tripled,

that all is not perfect in the manufacture or standardization of the product, but that viosterol is still a remarkable curative agent, reliable and very rapid in action.

HESS, A. F., *et al.* Newer Aspects of the Therapeutics of Viosterol (Irradiated Ergosterol). *J. A. M. A.*, 94, 25: 1885 (June 14), 1930.

Teaching Parents to Teach Health—That more must be said than "teach your little son to eat spinach" will be evident to all who read this brief and interesting statement.

GRUENBERG, S. M. Parent Education and Child Health. *Pub. Health Nurse*, 22, 6: 283 (June), 1930.

Human Milk Flow—Records of milk production show significant output changes from hour to hour and day to day which must have an appreciable influence on the nursing.

MACY, I. G., *et al.* Human Milk Flow. *Am. J. Dis. Child.*, 39, 6: 1186 (June), 1930.

Adult Serum and Measles—Immune adult serum was found to be almost as efficacious as convalescent measles serum. It has the advantage of being readily available and is free from the disadvantage of prejudice against the serum of strangers.

MORALES, E. G., and MANDRY, O. C. Relative Prophylactic Value of Convalescent and Immune Adult Measles Serums. *Am. J. Dis. Child.*, 39, 6: 1214 (June), 1930.

What We Know About Tuberculosis—The things we know about tuberculosis that are not so, and the things we know we don't know. Another unsettling paper, which really settles; the kind that the English do so well.

MUNRO, W. T. Some Tuberculosis Problems. *Med. Off.*, 43, 24: 267 (June 14), 1930.

Iodine and Goiter—This is noteworthy: "The administration of iodine to deficiently fed rats was definitely fa-

vorable to goiter production. . . . All grades of goiter were more common in deficiently fed rats to whose food iodine was added than in those to whose food iodine was not added."

McCARRISON, R. A Goiter Survey in Albino Rats. *Brit. M. J.*, 3621: 989 (May 31), 1930.

Epidemic Meningitis—Statistics of a Detroit epidemic of meningococcus meningitis (1928-1929) indicate an organism of unusual virulence. The fatality was highest in young children and adults; the colored population came in for more than its share.

MORTON, J. F., and GORDON, J. E. Meningococcus Meningitis in Detroit, 1928-1929. *J. Prev. Med.*, 4, 3: 207 (May), 1930.

Controlling Infectious Diseases—That doubts exist in the mind of the British Medical Officer of Health about the infallibility of our conceptions of isolation, disinfection and immunization will seem strange to American sanitarians who are wont to be so sure in their beliefs.

MUIR, W. A. The Administrative Control of Infectious Diseases. *J. Roy. San. Inst.*, 50, 12: 717 (June), 1930.

Syphilis Control Through Coöperation—Eloquent pleading by a master for an effective coöperation between practicing physician, public clinic, and other properly associated agencies.

STOKES, J. H. The Coöperation of the Practitioner and Organizational Forces in the Control of Syphilis. *New Eng. J. Med.*, 202, 23: 1087 (June 5), 1930.

Public Health Administration—The author says: "I deem it more profitable to consider the broad basic principles of public health administration rather than the details of procedure." He considers them excellently.

McLAUGHLIN, A. J. Public Health Administration. *Pub. Health Rep.*, 45, 21: 1191 (May 23), 1930.

The School Child's Welfare—It appears that there is much that is wrong with the up-to-the-minute educational program. The author points the dangers to the school child's health and urges their correction.

VAN DER BOGERT, F. Education, Health, and Health Education. New York State J. Med., 30, 12: 708 (June 15), 1930.

Victor Clarence Vaughan—The life and works of this great leader in public health are fittingly portrayed in a series of articles in a memorial num-

ber of the magazine of which he was the first editor-in-chief.

VAUGHAN, W. T., *et al.* Victor Clarence Vaughan. J. Lab. & Clin. Med., 15, 9: 817 (June), 1930.

Gonorrhea Prevention—The status of gonococcus infection, what we are doing about preventing the spread of the disease, and what we ought to be doing about it are all excellently told.

PELOUZE, P. S. The Prevention and Treatment of Gonorrhea. New Eng. J. Med., 202, 26: 1233 (June 26), 1930.

NEWS FROM THE FIELD

NATIONAL LEPROSARIUM AT CARVILLE

THE National Home for Lepers maintained by the U. S. Public Health Service at Carville, La., admitted 49 new patients during the year. The average for the year was slightly more than 300 patients. Nineteen patients were released as no longer a menace to the public health; 6 additional patients complied with the requirements for parole, but owing to their deformities and disfigurements which could not be cured, they elected to remain in the hospital rather than be subjected to the hardships and humiliations which are frequently the portion of many paroled lepers.

Chaulmoogra oil, by mouth, was used as routine treatment in 137 patients, the dosage ranging from 9 to 375 drops daily. One hundred and eighty patients are taking hypodermic injections of a special derivative of chaulmoogra oil. Dental work has continued. Supplementary treatment by means of physiotherapy and special light treatments are also given.

TEXAS TUBERCULOSIS ASSOCIATION

AT a meeting on June 16, the Texas Public Health Association changed the name of that organization to the Texas Tuberculosis Association.

NEW YORK STATE PUBLIC HEALTH COMMISSION

THE first meeting of the Special Public Health Commission recently appointed by Governor Franklin D. Roosevelt was held at the Academy of Medicine in New York City on June 5. Dr. Livingston Farrand, President of Cornell University, as Chairman of the Commission, presided. The Governor's

purpose in appointing this Commission is to have a study made of the public health needs of the state and of the working of the various state and local health authorities and their relations one to the other. It is 17 years since a similar Governor's Commission in New York brought the state to the front rank in this important field.

Among the major topics to be considered are: adequate hospital and medical care for the sick; development of full-time local health service on the county basis and for the larger cities; and the future needs in mental hygiene.

The studies of the Commission will be devoted to making available to the people of the state the practical application of every proven means of health protection and disease control.

NAMED ON WHITE HOUSE COMMITTEE

DR. Theodore B. Appel, Pennsylvania State Secretary of Health, has been appointed a member of the public health administration committee and a member on the sub-committee of state health organization on President Hoover's White House Conference on Child Health. Dr. Mary Riggs Noble, chief of the preschool division of the State Health Department, is on a committee of medical care for children, and Dr. C. J. Hollister, chief of the dental section, is a member of the technical advisory committee on dental hygiene in schools.

GLOVERSVILLE PHILANTHROPIST DONATES FUNDS FOR PUBLIC HEALTH WORK

LUCIUS N. Littauer, Gloversville glove manufacturer and philanthropist, has presented \$25,000 to Simmons College of Boston for the purpose of

broadening the scope of its work in public health. Mr. Littauer has advanced other large sums for research in pneumonia and the chemotherapy of cancer.

SCIENTIFIC EXPEDITION INTO BORNEO

DR. Bruce Magill Harrison, professor of biology at the University of Southern California, is spending the summer in the interior of Borneo on a scientific expedition sponsored jointly by the University of Southern California and Universal Pictures Corporation.

Dr. Harrison, who has had many years of preparation in biological research, has given valuable service in the division of biological sciences at the University of Southern California, has revealed rare ability for the undertaking of so important a task as this expedition.

UNIVERSITY OF SOUTHERN CALIFORNIA

DR. Wilder Dwight Bancroft, professor of chemistry at Cornell University and editor of the *Journal of Physical Chemistry*, gave the dedicatory address when the Hall of Science of the University of Southern California, the final wing of which has recently been completed, was formally dedicated on June 6.

FEDERAL BUREAU IS ORGANIZING TO ENFORCE PRODUCE LICENSING LAW

RULES and regulations for the administration of the Perishable Agricultural Commodities Act for the licensing of commission merchants, dealers and brokers, which was signed by President Hoover June 10, are being prepared by the Bureau of Agricultural Economics.

This law, intended to suppress certain unfair and fraudulent practices in the marketing of fresh fruits and vegetables in interstate and foreign commerce, requires the licensing of commission merchants, dealers, and brokers. All persons subject to the Act who plan to be in business on and after December 10,

1930, must obtain licenses from the Secretary of Agriculture.

LULU HUNT PETERS DIES

DR. PETERS on her way to London to attend a meeting of the Royal Sanitary Institute contracted pneumonia, and died in a nursing home in London on June 28. She was a member of the American Public Health Association and was travelling in company with the A. P. H. A. delegates enroute to Dresden.

She is well known for her writings on dietetics. Her best known book is *Diet and Health with Key to the Calories*.

Dr. Peters was decorated by both the Serbian and Albanian Governments for post-war child welfare and public health work in the Balkans, under the American Red Cross. She was a member of many medical organizations.

NEW MEXICO PUBLIC HEALTH ASSOCIATION

THE 6th Annual Meeting of the New Mexico Public Health Association was held in Albuquerque, June 3 and 4. The following officers were elected: *President*, Dr. J. G. Holmes, Alamogordo; *Vice President*, Marie A. Brunk, R.N., Las Cruces; *Secretary-Treasurer*, Paul S. Fox, C.E.

The next annual meeting will probably be held in May, 1931, in Santa Fe.

VACCINE TO CURE COLDS

DR. J. A. Pfeiffer, associate of the University of Maryland Medical School, believes he has discovered the micrococcus that causes the common cold, and that he has succeeded in separating it and making a vaccine that will immunize the patient from one to three years. This is the result of seven years' research.

WILLIAM L. STEVENSON

ON June 2, Franklin and Marshall College at Lancaster, Pa., con-

ferred upon William Lawrie Stevenson, Chief Engineer of the Pennsylvania State Department of Health, the honorary degree of Doctor of Science. Mr. Stevenson is a member of the class of '97 of the University of Pennsylvania and the early years of his work were with the City of Philadelphia, where from 1908 to 1918 he was assistant engineer in executive charge of experimental and design work on sewage treatment. During the World War, he was Sanitary Engineer for the U. S. Shipping Board and in charge of their Clearance Bureau at Philadelphia. Since 1919, he has been with the State Department of

Health and since 1922 Chief Engineer. He is a Fellow of the A. P. H. A., Public Health Engineering Section.

JANE H. RIDER

ON June 4, the University of Arizona conferred upon Jane H. Rider, Director of the Arizona State Laboratory, the degree of Civil Engineer for outstanding work along public health engineering lines in Arizona. Miss Rider is a graduate of the University. Since 1913 she has been with the Arizona State Board of Health Laboratory and director since 1919. She is a member of the A. P. H. A.

PERSONALS

DR. JOHN O. McREYNOLDS was elected to the presidency of the State Medical Association of Texas recently.

DR. HAROLD H. GOLDING has been elected Health Officer of Peekskill, N. Y.

DR. EDWARD A. LANE, formerly assistant director of the Division of Communicable Diseases, Massachusetts Department of Public Health, has recently become director of communicable disease control of the Westchester County Health Department, N. Y.

DR. WILLIAM E. BULLARD, Health Officer of Larchmont and Mamaroneck, N. Y., died recently at Saratoga Springs.

DR. JAMES W. DOUGLASS, Health Officer of Ava, N. Y., died recently.

DR. JOHN B. WEST, Washington, D. C., sailed in June for Abyssinia, where he will become physician to the emperor of Ethiopia.

DR. GEORGE R. ENLOE, Fort Worth, Tex., was elected president of the Texas Railway Surgeons' Association at its annual meeting, May 5.

CONFERENCES

August 26-28, Eighth Texas Sanitarians Short School, held with Texas State Department of Health and the City of Amarillo, Amarillo, Tex.

September 8-12, American Congress of Physical Therapy, St. Louis, Mo.

September 29, week, National Safety Council, Chicago, Ill.

October 11-19, National Dairy Exposi-

tion, St. Louis, Mo.

October 20-25, American Hospital Association, New Orleans, La.

October 22-24, International Association of Dairy and Milk Inspectors, Cleveland, O.

October 27-30, American Public Health Association, Fort Worth, Tex.

Summer Problem No. 3—DIARRHEA

AGAROL is the original mineral oil—agar-agar emulsion with phenolphthalein and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

Next to constipation, fermentive diarrhea is a most frequent problem in summer, especially in children and the aged. Thorough and regular elimination need consideration.

AGAROL

the original mineral oil and agar-agar emulsion with phenolphthalein, will prevent stasis, maintain normal elimination. No alkali, alcohol or sugar to cause difficulties. And Agarol is so palatable that children take it gladly.

Two regular size bottles are at your service for the asking. Send for them.

The Pan American Sanitary Bureau

BOLIVAR J. LLOYD, M. D.

*Medical Director, U. S. Public Health Service; Assistant to the Director,
Pan American Sanitary Bureau, Washington, D. C.*

THE growing importance of the relations of the peoples of each American Republic with those of every other makes it incumbent upon all Americans, North, Central and South, to become fully informed of these relations and to be informed particularly with regard to questions of an international character. The object of this paper is to sketch briefly the origin and development of the work of the Pan American Sanitary Bureau and the closely related Pan American Sanitary Conferences.

The Pan American Sanitary Bureau is a permanent international health organization in which all of the American republics are represented and to the support and maintenance of which they all contribute funds in proportion to their populations. The bureau is concerned in maintaining and improving the health of all of the people of these 21 American republics and also in preventing the occurrence and spread of transmissible diseases in international commerce, particularly the international commerce of the republics concerned. It is composed of members chosen from different American republics, who meet periodically, and of a force of employees who, under the supervision of the Director of the Bureau, are daily occupied in carrying on its work. Its home is in the building of the Pan American Union in Washington, D. C., and it is the executive organ of the Pan American Sanitary Conferences.

The Pan American Sanitary Conferences are composed of delegates from all of the American republics, who meet once in 2 to 4 years; elect the officers and members of the Directing Council of the Sanitary Bureau; and spend from 1 to 2 weeks in discussing and resolving international sanitary problems, particularly of the Western Hemisphere, and local sanitary problems of general interest. Since

their inception in 1902 there have been 8 Pan American Sanitary Conferences held in various American Republics.

For many years prior to the creation of the Pan American Sanitary Conferences and the Sanitary Bureau, statesmen, meeting in international conferences, treating of questions of a general nature, blindly attempted the solution of the vexing questions of international quarantines and the spread of such diseases as plague, cholera and yellow fever in international commerce, without, however, being able to improve general health conditions or obviate the drastic quarantines which would invariably follow the appearance of one of these diseases in some important commercial port. Gradually there dawned on the members of these general conferences the fact that the protection of the public health, involving as it does the prevention of the spread of communicable diseases, is a matter which must be dealt with by men who are specially trained in such work.

This opinion was crystallized and expressed in Sections 5, 6 and 7 of the Resolutions of the Second (general) Pan American Conference of American Republics, which met in Mexico City in 1902. These resolutions provided for the holding of international (Pan American) sanitary conferences; for the establishment and perpetuation of an executive body dependent upon these conferences—the Pan American Sanitary Bureau—and for funds for its maintenance, each American republic contributing to its support, according to the number of its inhabitants.

The officers and members of the Pan American Sanitary Bureau (known as the Directing Council) are elected by the Pan American Sanitary Conferences. The members of this Council, as chosen by the last conference, which was held in Lima, Peru, in October, 1927, are as follows:

Honorary Director, Dr. Carlos Enrique Paz Soldan, Professor of Hygiene in the Faculty of Medicine, Lima, Peru; *Director*, Dr. Hugh S. Cumming, Surgeon General, U. S. Public Health Service, Washington, D. C.; *Vice-Director*, Dr. Mario G. Lebrede, Director of "Las Animas" Hospital and Chief of the Section of Epidemiology, National Department of Health and Welfare, Havana, Cuba; *Secretary*, Dr. Sebastián Lorente, Director of Health of the Republic of Peru, Lima, Peru; *Members*: Dr. Solón Núñez F., Secretary of State for Health and Social Welfare, Republic of Costa Rica, San José, Costa Rica; Dr. Ramón Báez Soler, Sub-Secretary of State for Health and Welfare, Santo Domingo, Dominican Republic; Dr. Justo F. González, Professor of Hygiene in the Faculty of Medicine, Montevideo, Uruguay; Dr. João Pedro de Albuquerque, Director of Quarantines, National Department of Health, Rio de Janeiro, Brazil.

It is not possible, in a brief article, to give a detailed history of the work of the various Pan American Sanitary Conferences or of the Pan

American Sanitary Bureau. It should be recalled, however, that the first conference was organized in Washington in November, 1902; that it effected permanent organization by electing the members of the Sanitary Bureau, the first permanent organization of its kind; and that it cast into discard all previous quarantine measures directed against yellow fever, voting to base future measures for the control of this disease on the fact, which had recently been demonstrated, that yellow fever is conveyed in nature only by the bite of an infected mosquito.

The Second Pan American Conference also met in Washington, in 1905. This body drafted and approved a sanitary treaty, or convention, which, in great measure, standardized international quarantine procedure in the Western Hemisphere, and which was not without effect on quarantine practices, in European and Asiatic countries. This treaty was known as the Washington Convention, and was the precursor of the present Pan American Sanitary Code, adopted at the Seventh Pan American Sanitary Conference in Havana, Cuba, in 1924.

The Third Sanitary Conference provided for the establishment of relations with the International Office of Public Hygiene, of Paris, and a system of coöperation between the two offices has been developed for the mutual interchange of information regarding sanitary conditions and the presence of quarantinable diseases in the principal ports and countries of the world. This information is exchanged by cable, and is, immediately upon receipt, released to the health authorities of all countries concerned.

The Fifth International Conference of American Republics, meeting in Chile in 1923, charged the Sanitary Bureau with the preparation of an International Sanitary Code. This was done and the code was approved by the Seventh Pan American Sanitary Conference at Havana, Cuba, in 1924.

The Sixth Sanitary Conference, held in Montevideo, Uruguay, in 1920, authorized the publication of the *Pan American Sanitary Bulletin*, a monthly journal of public health, printed in Spanish, Portuguese and French. This bulletin circulates among health officers and others connected with public health work throughout the American republics, but chiefly in Latin America.

In addition, the Seventh Conference made the Pan American Sanitary Bureau the central coördinating agency and the general collection and distribution center of sanitary information to and from the American republics. In order to carry out this work, the Sanitary Bureau was authorized to designate representatives to visit and confer with the sanitary authorities of the various signatory governments on public health matters. Previous and subsequent authorizations provide for

traveling representatives to engage in such special coöperative work as may be agreed upon at the various conferences, limited only by the available funds and the expressed wishes of the coöperating governments.

Under a resolution adopted by the Fifth International Congress of American States, the Pan American Sanitary Bureau is authorized to call together in Washington, from time to time, the Directors of Health of the various American republics. The first such meeting was held in Washington in September, 1926, under the auspices of the Pan American Sanitary Bureau. Its chief work was the preparation of a program for the Eighth Sanitary Conference which was held in Lima the following year. The Directors of Health will meet again in Washington in 1931.

In addition to the duties which have been mentioned, the Sanitary Bureau publishes the reports of the proceedings of the sanitary conferences, and acts as a consulting bureau or source of information for health departments of the various republics. The way in which the office functions as a consulting bureau can best be illustrated by concrete examples. The following instances show the very close coöperation maintained.

1. A given food product manufactured in one republic and extensively sold in another caused considerable uneasiness with regard to its value and safety, and the propriety of its further use was questioned. The Sanitary Bureau was asked for pertinent information with regard to its production and composition. This information was obtained and promptly forwarded to the Director of Health of the country where the article was being sold.
2. After many years of absolute freedom from smallpox, this disease was re-imported into one of the American republics. Seven cases developed, which were promptly isolated, and an intensive campaign of vaccination and re-vaccination was immediately begun; the Director of Health was importuned to close schools, theatres and other public assembling places. He cabled the Sanitary Bureau for an expression of opinion with regard to the necessity for such drastic action. The opinion was expressed that the measures already employed, if thoroughly carried out, should be sufficient to control the disease, and that it was believed to be safe to await further developments. No further cases occurred from this outbreak.
3. At the request of a European government, the Office International d'Hygiène Publique cabled the Sanitary Bureau, asking if a reported increase of plague in a certain American Republic materially increased the danger from this disease to trans-Atlantic ports, and, further, the question was asked whether or not vessels sailing from the country infected could be considered safe upon arrival. The opinion was expressed by the Sanitary Bureau that the increase in plague did not materially increase the danger to trans-Atlantic ports. The Office International was further informed that, while outgoing measures were being enforced in the infected country, conditions were such that, if vessels arrived at trans-Atlantic ports with evidence of living rats on board, fumigation might reasonably be required of such

vessels. Three days later a vessel arrived at a European port from the country in question and, upon fumigation, 7 plague-infected rats were found.

The tour of duty of Dr. John D. Long and that of Dr. C. R. Eskey, Traveling Representative and Epidemiologist, respectively, of the Pan American Sanitary Bureau, are indicative of another type of coöperation in public health work. Dr. Long during the past two years has visited most of the capitals of the member republics. He confers with the National Directors of Health and with other high officials and aids them in solving sanitary problems of general interest, and advises with regard to needed legislation and public health organization and administration. During the past several months Dr. Long and Dr. Eskey have been actively coöperating with the authorities of the Republic of Ecuador in making epidemiological studies of, and in carrying on an intensive campaign against, bubonic plague. They will shortly transfer their activities to Peru where it is expected that similar work will be undertaken.

In conclusion, it may be said that, as a result of the work of the International Sanitary Conferences and the Pan American Sanitary Bureau, during the last 25 years, a better understanding has been brought about between the health authorities of the republics of America, thereby removing the necessity for the drastic quarantines which were so common in the early part of the present century, and at the same time affording greater protection of the public health. This spirit of coöperation has also fostered and directly aided in the extermination of quarantinable diseases in many ports and places where such diseases were formerly endemic.

Desert of the Lions—The Convent, Mexico City

How the Nurse Can Help the Health Officer to Get His Message Across*

From the Standpoint of the City

HENRY F. VAUGHAN, D. P. H., F. A. P. H. A.

Commissioner of Health, Detroit, Mich.

THE evolution of public health procedure since the establishment of the first officially organized municipal health department in the United States in the middle of the last century has been ably described by many authors. With the creation of the Metropolitan Board of Health of New York City under the guidance of Dr. Stephen Smith, Founder of our own Association, public health became administratively established as a recognized executive division of our city government.

In those pre-bacteriology days during which philosophic discussion played such a large part in determining the ill effects of epidemic conditions, it was but natural that the sanitarian placed great stress upon the influence of environment on man's health. Departments were organized to combat nuisances, to supervise systems of scavenging, to regulate packing houses and rendering plants and, in general, to supervise features of municipal sanitation. Some attention was paid to the improvement of water supplies and the disposal of sewage. These latter activities were, of course, successful in reducing the death rate from typhoid fever and other water-borne and filth diseases.

The features of the then existing health program were such as we would now group among those performed collectively by the city administration, which cannot be efficiently administered by the individual citizen. No heed was taken of the important rôle which we now know the individual plays in serving as a vector for the conveyance of infection. The researches of the bacteriologist revolutionized our conception of the mode of transmission of most epidemic diseases. Thus there was created a more logical system of quarantine and isolation based upon bacteriologic control. Such an administrative system made possible further progress in the control of disease but was not without its limitations as it was soon discovered that quarantine of

* Read at a joint meeting of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Fifty-eighth Annual Meeting at Minneapolis, Minn., October 4, 1929.

clinical cases in itself would not suffice to prevent the spread of infection. The healthy carrier, the mild case and the missed and undiagnosed case, played too large a part in the dissemination of infection. An appreciation of the limitations of quarantine together with the discoveries of the immunologist in the art of stimulating artificial protection against disease has finally led the public health administrator to an appreciation of the fact that education is the keynote on which all administrative policies of the modern health department should be built.

It is in this third developmental period of public health administration that the nurse is playing so important a part. While it is true that the layman continues to picture his health department as largely engaged in the supervision of epidemic diseases and the abatement of nuisances and offenses to the eye and nose, the administrator himself appreciates that his principal task is not to solve the vexing and annoying problems of the unusual but devastating epidemic, but rather to create an enlightenment in the public mind so that the individual citizen may appreciate his responsibility in keeping himself well and thus serving as a unit of a healthy community.

Public health administration is becoming more and more a problem in salesmanship. The city or county which is doing the most to teach its people the causes and means of control of disease and which is inculcating into the daily habits of its children the practice of hygienic living, is enjoying more vigorous health and is gradually lengthening the life of its citizens, thereby reducing its own death rate. There are many ways of selling health to the public. Popular health instruction through the medium of the printed page has done much to modernize the layman's conception of disease prevention. The daily or weekly newspaper as well as the health department bulletin, the movie, the radio and the lecture course plays an important part in the health education program. It can, however, be said without fear of contradiction that the most important single factor in teaching positive health is the public health nurse.

The *Appraisal Form* published under the auspices of this Association is generally recognized as an instrument which aims to express in terms of group judgment the value of the health program being administered by any city or county. An examination of this *Appraisal Form* would indicate that there is no division devoted exclusively to public health nursing. On the other hand a careful analytical review of the individual items incorporated in this measuring stick would indicate that the public health nurse is associated with activities which represent nearly 50 per cent of the entire score. The teaching value of the

public health nurse has become so well recognized that, in order to have a good local public health program, between 40 and 50 per cent of the appropriation of the health department should be devoted to a division of nursing. It may therefore be concluded that we as health officers have agreed that the public health nurse constitutes our most important asset in health education.

Are we using the resources and ability of the public health nurse to greatest advantage? If the housewife is considering the purchase of a new washing machine, she may obtain some impression of the type of machine she should have from advertisements which appear in newspapers or from hand bills left at her home, but, after all, the thing which convinces her above all things is the demonstration and sales talk of the vendor at the store. Salesmanship through demonstration and expression is the most profitable means of establishing opinion. As health officers we have public health nurses as our representatives entering every home of the community. We may have a specialized nursing service in which the individual nurse has been taught to function in but a limited field such as the control of the communicable diseases or visiting at the home of the tuberculosis case. We may have generalized nursing which is now recognized as a more effective and efficient form of service and in which the individual nurse may perform duties in each of the various divisions of the medical service such as tuberculosis, communicable disease, child welfare and school services. The success with which the nurse meets in selling herself to the housewife and selling her personality and her story to the family depends upon her tact, her judgment, her training and, above all, her method of self expression.

It seems to me that too many health officers have lost sight of the fact that the public health nurse is the sole representative of the health department who reaches the average home. The family will naturally think of the health department in terms of this representative whom they have met. Up to the present time it has been the sanitary inspector who noses about the premises to ascertain whether the garbage receptacle is properly covered and whether the premises are strewn with filth or trash which is considered inimical to health. No wonder that the citizen has conceived the health department as an organization of law-enforcing officials whose duty it is to make life miserable for those lax in the care of sanitary appurtenances and an organization which occasionally sends around an officer to tack up a quarantine sign and inflict further unwelcome hardships upon the family life.

The public should think of the health department in terms of the nurse as an educator, as a friendly guide and consultant to assist in

solving the many simple but perplexing problems which accompany motherhood and child-raising. Let us substitute the vision of the sympathetic nurse for the unwelcome shadow of the law-enforcing officer. Some health departments have been endeavoring for the past few years to transfer the supervision of nuisances which are merely esthetically unpleasant in contra-distinction to those conditions of our environment which are inimical to our health to the police department of the municipality.

The health department because of the misconception which existed at the time when our official health organizations were first established, has fallen heir to many practices which are not rightfully its own. The public should look to the police department for matters of police protection including the safeguarding of the human sensory system against nuisances created by others. The citizen should look to the health department to satisfy the thirst for knowledge regarding disease prevention and vigorous health.

Are our nurses properly instructed so that they can serve as the sole representatives of the health officer in the home? They should know something about their own department, its purposes and aims and about public health in general. They should have some knowledge of vital statistics; there should be some conception of the meaning of death and birth rates. They should not be expected to learn a long list of figures which of themselves would be rather dry and uninteresting, but they should know whether 15 per 1,000 is a high or low death rate, and whether 40 per 1,000 births is a high or low infant death rate. They should have some knowledge of what the city is doing to supervise its milk and food supply. They should know what is being done in the field of sanitation and industrial hygiene, whether poor housing facilities have any relationship to ill health, and if so what are the features of ill-housing which most closely affect the incidence of disease. In short, the public health nurse should be conversant with the various activities of not only her own health organization but also those other organizations, whether official or nonofficial, which are assisting in the local health program.

Every health department should have a well established program whereby the new nurse receives instruction in public health administration and in the various organizational divisions of health work. These courses of instruction should be compulsory not only for new nurses, but a shortened course of instruction should be given to the older nurses in order that they may be kept in constant touch with newer developments and posted concerning the changes in departmental policy. If a program of this character is not effectively car-

ried forward by the health officer, he is missing a wonderful opportunity to sell public health to the people of his community.

Dr. Hastings has frequently made the statement that in order to be successful as a teacher of health the nurse must be a good conversationalist. I have heard Dr. Hastings state that he was not primarily interested in seeing the credentials of the new nurse employed by the Toronto Health Department, although it goes without saying that the credentials must be of the highest in order to obtain appointment in that organization, but he was particularly interested in having a 5-minute conversation with the new nurse to ascertain her ability for self expression. We are not suggesting that the public health nurse become an incessant talker or even a mechanical doll, but we are suggesting that she be taught the rudimentary facts of public health administration seasoned with much information of local application so that she may intelligently act as a saleswoman for the health department.

Increased Incidence of Epidemic Poliomyelitis in Southern California

THE California State Department of Public Health¹ recently reported a steadily mounting incidence of acute anterior poliomyelitis. Statistics were quoted for January, February, March, April, and the first three weeks of May, 86 cases in all being reported. Since then, 151 cases have been reported, making a total of 237 from January 1, 1930, to date. Further analysis as to age groups affected of 131 cases in June so far, indicates that 75 per cent are over 5 years of age. This brings the age group well within those attending summer camps, thereby constituting at this time a public health problem of no mean consequences. Moreover, this disease manifests itself ordinarily in the late summer and fall and increased incidence in early summer is generally an epidemiologic indication of the disease reaching epidemic proportions.

It is extraordinarily interesting to note that approximately 85 per cent of the cases were reported from Riverside, Orange, San Bernardino, San Diego and Los Angeles Counties. Furthermore, under such conditions, it is necessary that physicians scrutinize with all suspicion, any illness, particularly of the respiratory or digestive tract, in the affected age groups for the probable incidental paralysis may not occur in many cases. The control measures are well established but their effectiveness is uncertain mainly because of the healthy carrier.

Animal Infections with Bacteria of Genus *Brucella* and Their Relation to Undulant Fever of Man*

J. TRAUM

Veterinary Science Division, Agricultural Experiment Station, University of California, Berkeley, Calif.

YOUR Program Committee has asked me to discuss the deKruif article which appeared in *The Ladies' Home Journal* of September, 1929. I advised them that I would rather discuss with you what is known concerning the disease in animals caused by *Brucella* organisms, with special reference to its relation to undulant fever in man, and only incidentally refer to the deKruif article. This seems desirable, because, after stripping the article of its romance, exaggerations and embellishments, and after the omissions have been taken into consideration, we find that deKruif is, more or less, telling the truth.

I am glad that his article has made it possible to acquaint the reading public with the accomplishments of Alice Evans, who had already been recognized and honored by national and international bodies interested in bacteriology, medicine and public health. Aside from the opportunity to pay this well-deserved tribute to Miss Evans, the good done by the deKruif article is very questionable.

In various professional and scientific meetings and publications for the past three or four years, the attention of those interested in public health has been called to the necessity of recognizing and studying undulant fever in America, and epidemiologists and laboratory workers everywhere have been making studies. Provisions to safeguard the public health against infection have been considered and some put into effect. *The Ladies' Home Journal* article of September, 1929, may do considerable harm by forcing those making studies of undulant fever to express opinions or make regulations not supported by sufficient data.

In 1905, the British Malta Fever Commission¹ presented satis-

* Presented at a joint meeting of the Health Officers' and Dairy and Milk Inspectors' Sections at the 12th Annual Meeting of the League of California Municipalities, Oakland, Calif., October 9, 1929.

factory evidence to prove that goats' milk may be infected with a virus which is responsible for Malta or undulant fever in man, and that most of the cases in man were contracted by handling and drinking such milk.

After this report appeared, it became a rather general practice to attempt to connect all cases of illness showing symptoms which resembled those of Malta fever to the drinking of goat's milk or to other direct or indirect association with those animals. When this was not possible, especially in countries where it was not endemic, the disease often went either undiagnosed or wrongly labelled; in fact, in such places, Malta fever was most often not even considered, because, it was argued, there were no goats; or there had been no contact with goats; or there was no infection in goats and, therefore, it could not be Malta fever. Serum tests were seldom made. A complete change of attitude has taken place, first, in this country and then in others. Let us briefly trace the reason for this change of attitude.

After Smith and Fabyan² and Schroeder and Cotton³ demonstrated that the *Brucella abortus* organism may be eliminated in the milk of some infected cattle, and that this organism was capable of inducing very pronounced lesions in experimental guinea pigs, it was naturally thought by a good many that possibly it was also pathogenic for man, and some evidence was gathered as early as 1911⁴ and 1913⁵ that such was the case. There was no thought of the relation of the abortion organism to undulant fever in man. Kennedy,⁶ in 1914, reported the finding of agglutinins for *Micrococcus melitensis* in the milk and blood serum of cows.

Even after Miss Evans called attention to the similarity between the organism causing abortion in cattle and that causing Malta or undulant fever in man, little evidence of the pathogenicity of the bovine abortion organism for man was brought forward. The medical literature of various countries for five or six years after Miss Evans's discovery contained suggestions⁷; in fact, fairly good circumstantial evidence⁸ indicates that such was the case. It was not until Keefer,⁹ of Johns Hopkins Hospital, reported a case of undulant fever in one of the laboratory assistants, who had had no dealings with cultures, that the fact was definitely recognized that the source of the undulant fever infection in man may be other than caprine. This report was followed by more evidence presented by Carpenter and his associates,^{10, 11} * and from that time the literature in this and other countries has been full of direct and indirect evidence showing that the goat can

* Italian investigators Viviani and Ficaí and Allesandrini, at about this time, reported similar findings, but owing to the fact that Malta fever infection in goats exists in that country, their reports did not attract so much attention as the American reports.

no longer be held alone responsible for undulant fever in man, but that the cow and the hog must also be given serious consideration as sources of the virus.

An effort has been made to separate and differentiate the various organisms belonging to the genus *Brucella*. This has been beset by a great deal of difficulty, and at present it is far from being satisfactorily solved. However, it may be stated now that at least three varieties or groups or species of the *Brucella* organism are being recognized by many. These are *Brucella melitensis*,* the old *Micrococcus melitensis* of Malta fever; *Brucella abortus*,† the most common cause of infectious abortion of cattle; and *Brucella suis*, the cause of placental infection and abortion in swine.

A discussion of the incidence of infections with one or more of the three varieties or species of *Brucella* organisms in man and animal may aid us in establishing the proper relationship of the disease in animals to that of man.

INFECTIONS IN MAN DUE TO BACTERIA OF GENUS BRUCELLA

Infections with all three varieties or species of this organism have been found in man.¹² For the present, we can dispense with a discussion of the *Br. melitensis* because this organism has long been accepted as the proven cause of undulant fever and, besides, we are concerning ourselves principally with human infections in localities where this variety is not supposed to exist. Miss Evans,¹³ and I believe others, have identified *melitensis* organisms from human cases where the goat was eliminated as the source of the infection.

Regarding human infections caused by the other two varieties, a great deal of evidence is accumulating, some of it very convincing, while some is not. There is, however, only a meager amount of data which enables us to separate the bovine from the porcine infections in human beings. Huddleson¹² typed 35 human strains belonging to either one or the other of these two species and grouped 20 as *Br. abortus*, and 15 as *Br. suis*. I desire to emphasize that his methods of classification are not yet generally accepted and the number of strains examined is not large enough to permit general conclusions. It would not be amiss to emphasize also that variety does not necessarily indicate the source—this will become clearer from further discussion. These 35 human strains came from Rhodesia, South Africa, and from portions of the United States where the goat was not a factor in disease in man.

* Miss Evans prefers *Brucella melitensis* (variety A).

† and *Brucella melitensis* (variety *abortus*).

BRUCELLA INFECTION IN ANIMALS

Cases of *Br. melitensis* infection in sheep, horses, mules, dogs, cats, rats and even chickens have been reported¹⁴ from various Mediterranean countries. Whether these were due to *Br. melitensis* or to other varieties of Brucella must at present remain unanswered. Infections in practically the same group of animals have been reported as also being caused by *Br. abortus*.^{15, 16} Such cases due to either variety are very rare and are, therefore, of no great consequence in transmission of the disease to man. That infections in these animals occur is, however, worth bearing in mind.

Goat—That *Br. melitensis* infects this animal has been known since the British Malta Commission issued its report. The effect of this virus upon the goat is variable. As a rule, no ill effects may be noticed; at other times, abortion and mastitis in the female and orchitis in the male have been observed. Of interest is the fact that, in spite of the apparent good health of the infected animal, the organisms in large numbers are eliminated with the milk. Some authors¹⁷ claim that the goat never rids itself of the infection. The urine of a large number of infected goats also disseminates the virus, and many cases of human infection are traced to this excretion.

Rare cases of goat infection with *Br. abortus*¹⁸ have been reported, and probably more intimate exposure to this virus would cause more numerous infections. This possibility must be considered in making regulations concerning the sale of goats' milk in localities where bovine infectious abortion is prevalent and melitensis in goats is not present.

Swine—Huddleson¹² examined 20 strains from European and American infected swine, and all were placed in his *Br. suis* group.

The infection by this organism produces in swine a clinical picture more or less like that caused by melitensis in goats. They may be infected and show no ill effects. Infected animals may show placental and fetal infection with or without abortion. The organism may be eliminated in the milk. Males may have orchitis.

The disease has made its appearance in a limited way in California and in some of the mid-western states. In Europe, its distribution is even more limited than in the United States.*

This infection in swine is of only general interest to dairy and milk inspectors. By health officers and epidemiologists, it should be given careful and serious consideration in their efforts to trace the source of infection in human beings, since the variety infecting swine is con-

* In personal correspondence, Axel Thomsen advised K. F. Meyer of a serious epizootic of abortion in swine in Denmark. Cultures forwarded to Dr. Meyer were found by him on preliminary tests to be like our *Br. suis*.

sidered by some investigators^{18, 19} as an important source of undulant fever in man in sections where *Br. melitensis* infection is not endemic.

Cattle—The infection in this species is no doubt of greatest importance to milk and dairy inspectors, because of its wide spread, because of the frequency with which this source has been justly and often unjustly associated with undulant fever in man, and finally because it concerns directly your official duties.

Infections with all three varieties of *Brucella* have been reported in cattle. Of 96 strains isolated from cattle, Huddleson¹² classifies 86 as *Br. abortus*, 8 as *Br. suis*, and 2 as *Br. melitensis*. Miss Evans¹³ has also reported *melitensis* variety in cattle infections.

Agglutination tests on the serum from thousands of cattle in various parts of the United States showed that approximately 20 per cent have yielded positive reactions. From 30 to 50 per cent of these reactors, or from 6 to 10 per cent of the cattle, eliminated the organism in the milk. I believe that sufficient progress in controlling the disease has already been made to have considerably reduced these percentages.

In cattle, the effect of the virus is very much like that found in goats and swine. Cattle may show no indication of disease. Often infection reaches the pregnant uterus and induces inflammation of the placenta and fetus, resulting, in many instances, in abortion. This, as a rule, is not attended by any great inconvenience to the cow. Cattle may even give birth to apparently normal, full-time calves in normal manner and still have the infection in placenta and discharges, and in the udder and the supramammary lymph nodes. The infection generally leaves the uterus within 3 or 4 weeks—it rarely lasts longer—but may persist in the udder and associated lymph nodes for a longer period—in some cases, for years. However, a good proportion of infected cattle never show the virus in the udder or soon rid themselves of the infection in this organ.

Thus far, an attempt has been made to present briefly the conclusions and summaries of the available data bearing on the infection with *Brucella* varieties or species in animals and in man, and from these data we cannot escape the conclusion that, in countries or localities where *melitensis* infection in goats is not present, the infections of swine and cattle must be taken into consideration in hunting for the source of the infection causing undulant fever in man. To what extent each is responsible for such infection is not known, and the conditions under which it takes place are even a greater mystery.

It has already been pointed out that, in certain localities, the swine infection is considered an important source of the virus causing un-

dufant fever. In this connection the Keefer case, referred to early in our discussion and also made prominent in deKruif's milk article, is, from the epidemiological viewpoint, considered as possibly of porcine origin, since one of the duties of the patient had been the frequent collection of porcine fetuses from one of the Baltimore abattoirs. Smith¹⁸ studied the Keefer culture and found it to be like porcine strains in its pathogenic effects on guinea pigs. It may also be stated that several of Carpenter's human strains,²⁰ apparently from milk-borne infections, are classified as *Br. suis*.

I have not attempted to analyze the large bulk of evidence collected in many portions of this and other countries to connect cow's milk with undulant fever in man. Some of it would be thrown out as insufficient to convict—some, however, is very convincing.

The fact that the infection in cattle is so widespread and affects so large a proportion of our cattle, and that such large numbers of our population are exposed to cattle infection, either by coming in contact with placental or fetal tissues which teem with abortion infection, or by consuming raw milk, cream or other raw milk products, which have resulted in comparatively few infections in human beings, has caused and still causes many to hesitate to accept cattle infection as a factor in the cause of undulant fever. These conditions simply indicate that man is very resistant to the bovine virus; nevertheless, the evidence now at hand forces one to the conclusion that certain infected cattle eliminate organisms belonging to the genus *Brucella*, which, under conditions not yet definitely understood, are capable of inducing symptoms of undulant fever in certain especially susceptible individuals.

PREVENTING INFECTION IN MAN FROM BOVINE SOURCES

It has already been established by controlled laboratory experiments that pasteurization,²¹ if carried out according to the laws of California, which designate 140–145° F. for 30 minutes, will destroy the varieties of *Brucella* discussed in this paper. The *melitensis* and *abortus* species are not killed at 140–142° for 10 minutes, but are killed in 15 minutes. The porcine variety is a little more resistant and requires 20 minutes at 140° or 15 minutes at 142° to make it no longer viable. At 145°, all three varieties are destroyed in 10 minutes.

I wish to emphasize the fact that I have always been, and am at present, a proponent of efficient pasteurization as a method of making our general milk supply free from pathogenic organisms for human beings. There are, however, certain people who desire to drink raw

milk and certain physicians who recommend it; also there are certain localities in which pasteurization cannot be efficiently carried out. For this group, an effort is being made to provide, if possible, a supply of raw milk which will be free from *Br. abortus* organisms. Let us examine the known facts to see if that is possible.

It has already been stated that approximately 20 per cent of our cows are affected with abortus infection. It has been estimated from a fairly large number of guinea pig inoculations with milk that from 30 to 50 per cent—in some cases higher—of animals that react to the agglutination test will eliminate this organism, making about 6 to 10 per cent of our cattle that are eliminating organisms in their milk.

The work of Schroeder and Cotton,²² Fitch and Lubbehusen,²³ and Carpenter and Parshall²⁴ shows that animals which do not react positively to the agglutination test for *Br. abortus* do not eliminate organisms in their milk. We²⁵ have found, however, that, in rare cases, an animal may be eliminating the organism and, at the same time, not react positively to the agglutination test. We have, however, further found that in 3 such cases one animal soon became a positive reactor and the other two ceased to eliminate the organism. King and Caldwell²⁶ obtained similar results. Thus, in a system of repeated applications of the agglutination test to cattle serums, as is now being practiced in eliminating the infection from herds, the chance of missing the rare cases which discharge the organism is further reduced.

If, in this connection, we take into consideration that the number of *Brucella* organisms in infected cow's milk is, as a rule, small,²⁷ that this is greatly diluted with milks from non-eliminating cows, and that even in the rare susceptible individual, epidemiologic studies indicate that large numbers of organisms are required to induce undulant fever, we may state that raw milk can be produced on a commercial scale which will not cause undulant fever in man.

Our present knowledge justifies such conclusion notwithstanding such statements as²⁸: "Carpenter has pointed out that many cows which eliminate the organism in the milk do not react to the test." I made inquiry of Carpenter concerning this point, and he replied that he had published no data which would justify anyone in drawing such conclusion.

The Medical Milk Commissions of the San Francisco Bay region and also of the southern part of the state have adopted a rule by which no animal which reacts to the agglutination test is permitted to supply milk to certified milk trade. It seems only reasonable that if certified raw milk is not considered suitable for human consumption unless it comes from animals that do not react to the test, ordinary raw milk

should also not be allowed on the market unless it comes from animals which do not react.

In this effort to protect the public against possible infection with cows' milk, the goats in many places have escaped attention. It seems that the least that can be done with goats' milk is to insist that it be pasteurized, if that is possible, or that it come from animals which do not react to the agglutination test. I have not been able to locate any data on the correlation of the agglutination reactions of goat serums to the elimination of the organism in milk.

Sterilization

THE fallacy of this claim of wholesale sterilization lies in the fact—and it is a fact—that the great majority of certifiable defectives are not the progeny of mentally defective parents, but of apparently normal or subnormal yet more or less self-supporting citizens, whom no sterilization laws could touch or seek to touch. The majority of victims of mental infirmity come of families who are the subject of some mental instability; whose germ cells are in some way faulty, and who may only be carriers of defect *without themselves exhibiting any trace*. If every certifiable mental defective had been sterilized twenty or thirty years ago it would have made little appreciable difference to the number of defectives existing today.—Dr. Frank A. Gill, *Brit. M. J.*, July 5, 1930.

Mental Hygiene in a Public Health Program*

JAMES L. McCARTNEY, M. D.

*Chief, Division of Mental Hygiene, Connecticut State Department of Health,
Hartford, Conn.*

PHYSICAL hygiene is very closely interwoven with mental hygiene, which has as its objective the greater happiness and efficiency of the individual, and thus the mental betterment of the race. The boundary line between is hypothetical, although it was not until the last two decades that mental hygiene has been given an important place in the general campaign for the improvement and well-being of humanity. In the last analysis, the body is subservient to the mind, and will be ennobled or degraded according to the type of mind to which it gives habitat. The meteoric rise of the mental hygiene movement in the last twenty years is witness to its paramount importance in any public health program.

Every constructive movement has had the justification of an urgent need and this necessity has ever been the stimulus for practical and effective action. Unless these overwhelming needs are satisfied, human nature inevitably degenerates, and human aspirations are lost in chaos. Thus humanitarians, criminologists and health workers the world over are realizing the dire necessity for the improvement of the general health of individuals and races. There never existed a more true and striking need than that which is to be found in the present necessity for mental hygiene.

It is said that there are three types of lies—white lies, black lies and statistics—but there is fascination in statistics, and if carefully studied, they depict certain facts, and these show a real danger, which is more thrilling than the fictitious dangers found in many detective stories. Statistics from hospitals in the United States show that there are more persons mentally sick than physically sick in our hospitals. The admissions to these hospitals amount to 75,000 annually. One out of every 21 persons in the general population has been or will have been at some time in a mental institution, if not given proper mental hygiene to forestall the mental illness. This is even more

* Presented at the New England Health Institute, Boston, Mass., April 18, 1930.

graphic when we realize that 1 out of every 7 families shows a history of insanity. Thus we find that out of the 24,000,000 children now in our schools, at least 1,000,000 are destined to be blighted by mental disease, unless mental hygiene is applied; but it is encouraging to note that at least one-half of mental disease is preventable. Nevertheless, prevention does not consist in building more hospitals, nor does it imply the treatment of already well established and chronic diseases of the mind. Its program calls for the erection of protective measures many years before mental disease may be expected to develop.

Just as physical hygiene finds its most promising field among children, so human behavior or personality is most easily influenced in the right direction during its most formative period, that is, during childhood; yet, it is difficult to define clearly what is meant by personality, human behavior, conduct, or whatever you wish to call it. Perhaps, it can be best defined as the difference between an animal and a human, or rather it is the difference between animals and most human beings. Defectives who lack intellectual endowment can scarcely be credited with the possession of personality. Much controversy may therefore be avoided by speaking of personality as the sum total of the great number of sensory-motor reactions correlated by the mind or the voluntary responses of the individual to the environment.

All will agree that the functions of the mind are not separate or distinct entities but part of the correlated whole. The old psychology taught that the mind was composed of a number of cubby-holes, and each one was supposed to hold a special faculty, such as feeling, thinking, volition, etc., and was quite distinct from the others. This conception has become inadequate and so has been discarded.

Almost everyone knows that the body is made up of a great number of organs, each one of which has a certain function, and that the function of each of these must be timed in response to certain conditions and in proper relation to the other organs of the body, or it does not efficiently serve its purpose. The stomach must secrete its juices when food is introduced; the active brain must be supplied with an increased amount of blood; the kidneys and the skin must act harmoniously to excrete their waste products, and the respirations must increase on physical exertion. It is a function of the nervous system to organize the activities of the organs of the body so that they may be properly adjusted in relation to one another. This mechanism of pseudo-intelligent correlation rests in the vegetative nervous system, the simple reflex arc, the spinal cord and medulla; but under certain conditions may show the effect of the higher centers.

The outer layers of the cortex of the brain are thought to be the origin of thinking, and their functioning is interpreted as mind, as these functions regulate and control the actions of the individual as a whole. These functions learn how to react, and so are known as conditioned responses, but in order that these responses may be learned, the cerebral cortex must necessarily be brought into relation with the environment through the sense organ. If the person is to become an intelligent individual these responses must be coördinated, and the resulting conduct is the sign of personality.

In order that this conduct may be normal, the brain and the general nervous system of the individual must be healthy; otherwise, the adjustment of the individual to his environment cannot take place efficiently. If the individual is to adjust properly, it is necessary that he can profit from his experiences in the environment. The results of these experiences must be organized, associated and brought into relation with previous experiences, and the person must learn to transform these experiences into appropriate actions. As in physical processes, mental processes having once occurred, tend to recur in the same way when the same conditions are repeated.

Although it is important to take these fundamental facts into account, if an attempt to prevent or curb the incidence of nervous and mental disorder is to be considered, several other factors of prime importance must be noted. These are sound heredity, careful protection of the health of the mother during pregnancy, all possible care and skill at the time of delivery of the child, careful and sensible guidance through the first years of life, rational school training, proper supervision during the adolescent years, abstinence from drugs, sexual and alcoholic excesses, avoidance of syphilitic infection and other organic diseases which affect the nervous system, and, of course, prevention of conflict in general, anywhere in the environment.

Just as the principles of eugenics must be taken into account in the improvement of physical health, so necessarily this must be thought of when considering the possibilities of the inheritance of nervous or mental disorders. Where there is a possibility of hereditary taint, there should be no intermarriage, or certainly no children should be brought into the world from such progenitors. In most states, birth control advice cannot be given legally to this type of case, and in Connecticut it is even illegal to practice contraception. Realizing that there are types of mental disease and mental deficiency which have an hereditary tendency, a number of states, including Connecticut, have a law permitting sterilization under certain circumstances. While sterilization is of undoubted value in the prevention

of poor mental stock, the procedure can be logically recommended in only a very restricted group.

The health and environment of every prospective mother is a matter of vital importance to the mental hygienist. There has already been sufficient research work done to prove conclusively that the environment of the mother during the time that she is carrying the child definitely affects the child in utero. This may be shown by the sudden start that the unborn child gives when a sharp noise is made near the pregnant woman. If this is often repeated, the child of course does not get the necessary rest. Incidents in the emotional life of the mother, such as persistent worry, neglect, or other great emotional disturbances, and physical states, such as malnutrition, glandular dysfunction and renal disease, are found frequently in the prenatal history of children suffering from arrested development and cerebrospinal disorders. It is well to urge upon the prospective mother and her relatives that her whole physical and mental condition while she is carrying the child may have great effect upon the development of her baby.

Some children are born mentally defective, but this does not necessarily mean mentally diseased, although every case is a mental hygiene problem. Feeble-mindedness is a state of retarded mental development due to a number of causes, including heredity, injury at birth, and certain diseases. Feeble-mindedness, unless due to some physical condition, is not curable while, on the other extreme, under proper treatment glandular types show almost miraculous improvement. It must be remembered that certain individuals are judged to be feeble-minded because of defects of hearing, vision, etc., which give them the appearance of being slow and backward, while all that is necessary is to correct the physical defect in order to alleviate the erroneous impression.

Feeble-minded persons become social problems for the same reasons as other people. Barring bad environment and the lowest stages of feeble-mindedness, such as idiocy and imbecility, a feeble-minded person who is not afflicted with mental unbalance or some psychopathic condition has a fair chance, with the proper kind of training, to get along reasonably well in the community. Even the low grade defectives can be taught certain very simple occupations, much to their own benefit, with the result that it is easier to manage them in institutions. It is also possible to make them, to some extent, self-supporting in this way.

The importance of proper physical care of the child in the first months of life is recognized by all public health workers, but in no

less a degree is it important to follow with sensible training and discipline in the early years. It is recognized that the early environment makes a very definite imprint on the development, and it may be stated, without dispute, that many of the neuroses and psychoses of later life could be prevented if the child in its early years were guided sensibly with due regard to its emotional development.

It matters not whether the hereditary background be a simple neurasthenic, hysteric, or manic depressive personality, the family environment plays a very important rôle. There is a generally accepted opinion that heredity has a very big part in determining many of the mental diseases, but this belief is much too pessimistic to be accepted, for these predispositions many times can be counteracted, if not nullified by healthy environment. Every child at birth should be considered potentially normal, although it is important to watch with greatest care during the early, formative years, as he may show a tendency toward one of the neuroses or psychoses.

Children are normally imitative, and should they happen to be born to parents of the hysterical type, they are likely to imitate their performances, and become hysterical themselves. There is little use in instituting any form of treatment unless the hysterical child can be put under the charge, continued over a number of months or years, of an intelligent nurse, teacher or foster-parents, who will study its peculiarities and make a serious attempt to influence its behavior along natural, healthy lines.

In recent years special stress has been laid upon the earliest possible recognition of mental abnormality, as early diagnosis usually leads to the necessary steps to prevent mental disease later in life. This is the basic thought underlying the mental hygiene movement. It is the reason for the establishment of child guidance clinics, for careful personality studies, and for much of the social and psychological work that is now being attempted in the family, school, and industry. In all this work the assistance of the general medical man and the public health worker is needed, for they have in mind the physical well-being, and should also have the mental and moral development of the individual. They should know not only the child and the youth, but also the parents and their ancestry and should be willing to avail themselves of such facts as the social worker, psychologist or psychiatrist may provide. They should also be able to keep an open mind toward the many prevalent fads, but they should not be swept under by public enthusiasm.

From the physical side, as mentioned above, conditions may be present in the mother that will definitely affect the personality of

the child. Damaging toxic substances may be introduced through the walls of the placenta and a minute injury in the placenta may even allow the passing of a vast number of microorganisms into the child. If syphilis is found in the pregnant woman, she should be given intensive treatment; otherwise the child is likely to be a victim of neurosyphilis. It has been shown that tuberculosis, poliomyelitis, encephalitis and some of the other infectious diseases, or their toxins, may be transmitted to the child, causing definite damage to the nervous system, even before birth. It is, therefore, necessary to protect the mother carefully if the child is to be mentally healthy.

During labor, naturally the mother should receive first consideration, but unfortunately the physician or nurse does not always take sufficient cognizance of the actual injury that may be inflicted upon the child. Often its entire life is affected by improper obstetrical methods at the time of delivery, such as prolonged compression of the skull, protracted dry labor and unskilled instrumental delivery, which are responsible for many infantile cerebral lesions, especially the monoplegias and hemiplegias which may subsequently develop into epilepsy and which might well be prevented. If the public health worker is reminded of the fact that occurrences immediately before and during delivery not only may result in various forms of paralysis but may lead to something that is far worse, such as chronic epilepsy and idiocy, he or she will realize the obligations toward the child that is being helped into the world. These conditions resulting from the so-called birth accidents certainly are avoidable.

In recent years public health workers have become more and more aware of the fact that many of the diseases of childhood are apt to have neural sequelae. Most common of these are acute anterior poliomyelitis—occurring most frequently in children, but often in adults—epidemic cerebrospinal meningitis, and epidemic encephalitis, otherwise known as encephalitis lethargica. Since many of these diseases are extremely infectious, it is necessary to isolate the patients not only to prevent the spread of the disease, but also the almost inevitable mental conditions that follow.

Today mental hygienists are faced with a very grave problem in the number of post-encephalitis cases that are coming to their attention. But it has been found that the post-encephalitis syndrome need not necessarily be preceded by encephalitis lethargica, as some of the other high fever diseases, such as scarlet fever, often cause much the same "moral" deterioration. It should be emphasized here that the care of the patient suffering from any of these infectious diseases of the central nervous system plays an important part in the prevention

or restriction of the sequelae which are far more disastrous than the actual infection. In all these cases it is important to prolong the period the patient is in bed until every vestige of the inflammatory process has disappeared, and this should be followed by a very long-controlled, convalescent period with proper occupational therapy.

Syphilis as a precursor of nervous and mental disease is of paramount importance when it is realized that up to 73 per cent of all syphilitics develop neurosyphilis. Everyone with primary syphilitic disease should be considered potentially neurosyphilitic, and lumbar punctures for diagnostic purposes should be the routine rather than the exception. The prevention of neurosyphilis or general paresis, of course, means the persistent and thorough treatment of the primary disease. Because the malaria treatment of general paresis has shown such gratifying results, is no reason for delay in carrying out thorough treatment before any neurological signs develop.

There are a number of distinctive hereditary conditions; among these being Friedrich's disease, hereditary spastic paralysis, progressive muscular dystrophy, and amaurotic family idiocy. If anything can be done to prevent the development of these disorders it is only by ruling against marriage of individuals coming from families in which one of them has been prevalent. This of course necessitates a very careful family study and if the parties involved desire to marry they should be sterilized, as inevitably the disease will appear in their progeny. Some of them appear to be accompanied by endocrine disturbances and there is some question at present if immediate endocrino-therapy in new-born children from such families might not prevent the development of the disease later in life. When the presence of one of these diseases is established it is necessary to use every effort to counteract disturbances in normal locomotion and the general use of the limbs, which inevitably follow.

There are a number of functional disorders known as chorea and tics which apparently start on a definite physical basis, but become habits. It is therefore necessary to stop these conditions before they become established. At least one-fourth of these complaints seen in adults might have been prevented if they had been given thorough treatment in childhood. All sources of irritation should be removed, such as ill-fitting spectacles, irritating scars on the face or other parts of the body, ill-fitting collars and clothes, hair poorly cut and hanging over the eyes. Patience in training the patient to overcome these habits is a necessity.

So-called fainting spells and lapses of consciousness may be the first manifestation of the epilepsies, as may also be the convulsions of

early childhood. In no other type of disease is a complete physical examination of greater importance, for although the condition may be of emotional origin, it may be organic, and thus be starting a faulty habit pattern.

Disorders of the internal secretions play an important part among the preventable mental diseases. Of late years the physiological functions of the thyroid gland, the pituitary, the adrenal, the pancreas, and the sex gland have been studied so successfully that the use of these glands or extracts of them has distinct therapeutic and prophylactic value. Myxedema, cretinism or idiocy, hypo-pituitarism, various forms of distorted growth and various sexual abnormalities have been held in check or arrested in their extreme development by feeding the individual with one or the other of these glandular products. It is therefore very necessary to determine if there is an endocrinopathy present in the individual.

There are a number of emotional conditions which call for special attention. The obsessions of early childhood are most often based upon some experience, bad or otherwise, that the child has had, and which continues to hound him. Then there are so many individuals of abnormal habits seen in everyday life that the importance of checking such tendencies in early childhood cannot be stressed too strongly. Many physicians and public health workers do not seem to realize the effects of these emotions, for when a patient comes to them stating that he is afflicted with some physical impairment, and who in reality is suffering keenly, they often dismiss him with the statement that there is nothing the matter with him. This explains to no small extent the widespread use of cultists, such as chiropractors and others to whom these discouraged people so often go as a last resort, and getting attention, get relief.

Boys and girls of school age, and especially beginning with adolescence, are prone to mild mental disorders. Many of them are just nervous, some are hypochondriacal, and a considerable number are afflicted with a sense of inferiority, although this is by no means as common as the discussions on the "inferiority complex" would lead one to believe. In all such cases, it is a matter of the utmost importance that the home and the school environment be examined carefully and that the child in his relations to his family and to the other pupils at school be carefully determined. Personality studies will be most helpful providing the person conducting them shows a proper sense of proportion and does not exaggerate any complaints that are relatively unimportant. It is well to remember that every individual is expected to conform to conventional standards of behavior, and if he

cannot be made to do so it would be well to inquire into the reason why he is different from the average. In many cases, conditions have to be altered to meet the needs of a particular child, but it is well not to be too indulgent, and not to make too much ado over slight peculiarities in the behavior for this is likely to encourage the development of neurosis.

In children and in adults, speech disorders, headaches and insomnia are among the preventable complaints.

Among young adults, dementia praecox and manic depressive psychoses are the two conditions which cause more mental illness than any others, and it appears that although heredity may be a factor in these two conditions, environment or destructive experiences are the precipitating causes. In the adolescent period when usually the first great struggle for existence becomes manifest and the question of economic support first presents itself individuals are apt to subject themselves to unusual efforts. It is necessary that they realize that there are margins of safety and that a limit to endurance exists. Not every boy or girl is mentally fit to stand the strain of a college education. Certainly not all those who attempt to enter one or another professional career are fitted for such. If individuals are more carefully directed into the lines of work for which they are mentally and physically fitted, many of them will be prevented from later mental catastrophe.

The problem of the feeble-minded, the epileptic, neurotic or psychotic is but one phase of mental hygiene, as it is something which affects all persons. Nothing is more important than the right mental attitude toward life's problems in general. No one can grow up from childhood and live a life of ordinary length without conflicts, doubts, and problems which tend to make adjustment to life difficult. Some cope with these problems with reasonable success; others simply cannot find a level, and may develop any one of a number of mental abnormalities or kinks and twists which interfere with their happiness and efficiency, and even more with the happiness of those with whom they come in contact. Unfortunately, few have a working knowledge of the rules of mental health. They do not even know that there is a group of specialists in the medical profession equipped by experience and training to help those afflicted with these abnormal mental states. One of the important items in any public health program is to get over by every educational means possible, better knowledge of mental health, the importance of preventing bad mental habits in children, and knowledge of the facilities for handling such problems in the community.

Mental hygiene has also a definite relation to the problem of crime,

but it is possible here only to make reference to it. There are many persons being placed in jail, and others being convicted of crime and sent to state penitentiaries, who are mental cases, but not always recognized as such. Some of the more enlightened states make careful study of the inmates of the state penal institutions, in order to determine their mental condition, and, where necessary, are placing the mental cases in proper institutions. While psychiatry is certainly not the entire key to criminality, it does play an important and distinct part. Although this fact is not as yet fully accepted, it is hoped that the time is not far distant when it will no longer be customary to pit one "mental expert" against another in the court room. Fortunately, some states have a definite committee of psychiatrists to examine offenders when a question of mental disease is raised, and which can scientifically recommend the disposition of these cases.

Among the most ancient problems confronting the human race are those connected with home, marriage and domestic relations. At present our ideas on these subjects are undergoing a rapid transition in America and throughout the world. Ancient views and fixed traditions are giving way before clear thinking. There is a confused difference of opinion as to what should be discarded and what retained. Whatever may be the viewpoint on the subject of marriage and divorce, it is generally accepted that there are far too many divorces for the general good of society. A careful study of statistics during the last forty years shows that legal separation is on the rapid increase. In 1887, there were but 5.5 divorces to every 100 marriages, by 1919, this number had increased to 10, and since 1919, to more than 15.

It is not surprising that welfare agencies of every type are looking about for assistance in studying this trend toward wholesale divorce. They have come to the mental hygienist to inquire what, if anything, can be done to better the situation by means of mental hygiene. Experience has shown that mental hygiene is not a panacea for this situation, as it is not for most of the other mental maladjustments. In fact the presence of the "mental expert" in the criminal courts has occasionally hindered rather than aided the cause of justice, but, it must be added, this often is due to untrained "experts." There is a great dearth of trained and experienced persons, who are competent to handle the delicate temperament of the would-be divorcee. The harm that inexperienced hands may cause in attempting to cure a mental situation is very great, and may even cause greater difficulty by such mishandling. Over-zealous enthusiasts often attempt to do what lies beyond them.

Recently there has been some enlightening research work done on

the subject of family relations. It was found that the causes for divorce were in the approximate order of importance as follows: temperamental incompatibility, physical dissatisfaction, restraint of personal freedom, ill-health, jealousy, differences over children, economic difficulties, relatives and "everything wrong." All will agree that most of these causes are purely mental maladjustments. If to these items are added undue pride, abject poverty, mental defect, unstable temperament, chronic illness or a combination of these, one can realize some of the mental stresses that impel people to divorce, and it is only by the diminution of these persistent annoyances that anything can be done to prevent or lessen it. This may need the care of a mental specialist, for the successful mental clinician is able to secure the subject's coöperation and the full and confidential statement of the patient's grievance as no one else can. The mere fact that he has given voice to all his pet worries is often sufficient to set him on the road to a new adjustment, for it is often the pent-up, petty annoyances that gradually lead to a wider and wider rift, which eventually ends in the divorce court.

When unmarried youth has been taught the facts of mental hygiene which concern marriage and living together happily, there will be less fear when marriage actually occurs. Somewhere these people must get an understanding of the necessary "give and take" of married life, must reach some conclusion as to the degree of temperamental difference they can permit; must gain some sane and sound views on sex and its relation to a happy marriage; must appreciate the differences of opinion that are likely to arise over economic difficulties, children, relatives, and social and religious affairs. This is one of the problems which mental hygiene is now working on, and which should be given the concern of every public health worker.

It is evident that in any mental hygiene program it is very necessary to study the individual as a whole, socially, physically, intellectually and emotionally. This necessitates a thoroughly trained psychiatric social worker who can study the environment. This may be a trained nurse who has had experience along this line, who can go into the home or school environment and study the conditions under which the individual lives in order to help the diagnosis of the case, or to find what may have to be changed in order to help the person readjust himself to society. The physician has to make a very careful physical examination in order to determine that there is no physical abnormality or inferiority present. Then the psychologist is necessary to determine the inherent intellectual ability of the individual to make such an adjustment, and the psychiatrist, taking the facts as

found by the others, and studying the individual from the emotional angle, tries to digest all the material obtained in order to determine whether it is the heredity, the environment or the individual that needs readjustment. Thus, only, can mental hygiene hope to succeed, and thus it is apparent that no public health program is complete without a very careful mental hygiene program.

Mental Development of Feeble-minded Children

DURING a 9-year period, 86 children passed through a special school for defectives in Bath, and were discharged as follows: 27 per cent were passed to the statutory mental deficiency committee as imbeciles, that is to say, they proved unable to fend for themselves in life; 36 per cent were classified as low grade feeble-minded, probably unable to fend for themselves; and 37 per cent were considered able to fend for themselves.

The actual results up to the end of 1925 are known as regards 52 children, of whom 42 per cent are at work fending for themselves, 10 per cent are out of work, apparently failing to fend for themselves, 25 per cent are at home incapable of work, and 23 per cent are in institutions. The fact that 42 per cent of the children trained in this particular special school were able to find work, and that only 23 per cent had to be placed in institutions, is at least encouraging; but, even so, there can be little doubt that the colony system on a large scale is the optimal method of dealing with certifiable mental defect in the bulk.—Abstracted from *Brit. M. J.*, London, June 14, 1930.

The Prevalence of Syphilis

THE Massachusetts Department of Health, coöperating with the U. S. Public Health Service, has just published a bulletin dealing with the ravages caused by syphilis and gonorrhea. When one bears in mind that these diseases are very incompletely reported it will come as a shock to many that during the 8 years embraced in this study (1920-1927 inclusive) the *reported* number of cases of syphilis was very much greater than the reported number of cases of scarlet fever, diphtheria, smallpox, typhoid fever and tuberculosis. The actual figures given in the bulletin are as follows:

35,083 more cases of syphilis than of scarlet fever	(42 states) *
1,017,463 more cases of syphilis than of diphtheria	(42 states) *
390,268 more cases of syphilis than of smallpox	(41 states) *
1,122,580 more cases of syphilis than of typhoid fever	(41 states) *
78,570 more cases of syphilis than of tuberculosis	(21 states) *

* Only those states reporting both diseases were included.
